PROBLEM 1:  \textit{(Mystery Repeat Repeat Repeat Repeat: (22 pts))}

PART A \((12 \text{ pts})\):
Consider the following \textit{Mystery} method.

\begin{verbatim}
public int Mystery (String phrase)
{
    int pos = phrase.indexOf("e");
    int pos2 = phrase.indexOf("e", pos+1);
    System.out.println(phrase.substring(pos, pos+3));
    return phrase.substring(pos2).length();
}
\end{verbatim}

A. What type is the return value for the method \textit{Mystery}?
B. How many parameters are there?
C. For the call \texttt{Mystery('GoeDukeiea')}, list first what is printed as output and list second the return value.
D. For the call \texttt{Mystery('eeeee')}, list first what is printed as output and list second the return value.
E. Describe in words what the method \textit{Mystery} does.
F. Give an example value for phrase that will cause the function \textit{Mystery} to crash. Explain why it crashes.

PART B \((10 \text{ pts})\): Consider the following \textit{Mystery2} method.

\begin{verbatim}
public int Mystery2(ArrayList<Integer> numbers)
{
    int x = 0;
    for (Integer num: numbers)
    {
        if (num < 6)
        {
            x += num;
        }
    }
    return x;
}
\end{verbatim}

A. List the names of the local variables in \textit{Mystery2}.
B. What is the return type of \textit{Mystery2}?
C. Suppose values is an ArrayList<Integer> and has the values 8, 4, 9, 2 and 3 stored in this order from position 0 to position 4. What is the return value of the call Mystery2(values)?

D. Describe in words what the method Mystery2 does.

E. Explain why the ArrayList is of type Integer instead of type int.

PROBLEM 2: *(Don’t forget the middle: (8 pts))*

Complete the method InsertMiddle that is given two string parameters. The first string is a name consisting of a first name and a last name separated by one blank. The second string is a middle name. This method returns the name with the middle name inserted between the first and last name.

For example, InsertMiddle(“Sarah Forth”, “Go”) would return the string ”Sarah Go Forth”. You can assume that there is exactly one blank in name, between the first name and last name.

```java
public String InsertMiddle(String name, String middle) {
}
```

PROBLEM 3: *(Living on Campus: (10 pts))*

Consider the following two classes.

```java
public class Dorm {
    private String myName;
    private int myNumRooms;
    private int myNumFloors;

    public Dorm(String name, int numRooms, int numFloors) {
        myName = name;
        myNumRooms = numRooms;
        myNumFloors = numFloors;
    }

    public String getName() {
        return myName;
    }
}
```
public int getNumRooms()
{
    return myNumRooms;
}

public int getNumFloors()
{
    return myNumFloors;
}

public class AthleticDorm extends Dorm {

    private String mySport;

    public AthleticDorm(String name, int numRooms,
                        int numFloors, String sport)
    {
        super(name, numRooms, numFloors);
        mySport = sport;
    }

    public String getName()
    {
        return super.getName() + ": the " + getSport() + " dorm";
    }

    public String getSport()
    {
        return mySport;
    }

    public void setSport(String sport)
    {
        mySport = sport;
    }
}

A: Which of the two classes is the superclass?
B: Consider the following 4 sections of code. State if the two lines of code are valid or contain an error. If they contain an error, then state what the error is. If they do not contain an error, then list the corresponding output.

// 1.
Dorm dorm1 = new Dorm('Keohane', 80, 4); System.out.println(dorm1.getName());

// 2.
Dorm dorm2 = new Dorm('Blackwell', 60, 2); System.out.println(dorm2.myName);

// 3.
Dorm dorm3 = new AthleticDorm('Nelson', 60, 3, 'basketball'); System.out.println(dorm3.getName());

// 4.
AthleticDorm dorm4 = new AthleticDorm('Blumenhurst', 20, 2, 'volleyball');
dorm4.setSport('golf'); System.out.println(dorm4.getName());

PROBLEM 4: (Checkmate(42 pts))

Consider the class Player shown below to represent a chess player. Chess is a board game
played by two people. A Player stores information about a chess player including their name,
their rank (a number that is larger means the player is higher ranked, and 0 means they are
unranked.), and their grade in school, 1-13, with 13 meaning they are out of high school.
There is no grade higher than 13.

public class Player {

    private String myName; // name of player
    private int myRank; // rank of player
    private int myGrade; // grade player is in, from 1-13

    public Player (String name, int rank, int grade)
    {
        // code not shown
    }

    // return name of player
    public String getName()
    {
        // code not shown
    }

    // return rank of player
    public int getRank()
    {
        // code not shown
    }

    // return grade of player
    public int getGrade()
PART A (18 pts):

PART A1 (4 pts): Complete the constructor for the class Player.

    public Player (String name, int rank, int grade) {
    
    }

PART A2 (14 pts):

Complete the code for the following methods.

    // return name of player
    public String getName() {
    
    }

    // return rank of player
    public int getRank() {
    
    }

    // return grade of player
    public int getGrade() {
    
    }

    // increment grade of player by 1
    // except if grade of player is 13, do not change grade.
    public void incrementGrade() { // code not shown }
// change rank of player to "rank"
public void setRank(int rank)
{
    // code not shown
}

PART B (24 pts):
Consider the ChessTournament class that is listed below with an example.

public class ChessTournament {

    private ArrayList<Player> myPlayers; // list of all chess players

    public ChessTournament (Scanner input)
    {
        // code not shown
    }

    public static void main(String[] args) throws FileNotFoundException
    {
        String inputFileName = "chessdata.txt";
        FileReader reader = new FileReader(inputFileName);
        Scanner in = new Scanner(reader);
        ChessTournament Feb8 = new ChessTournament(in);

        System.out.println("Grade 5 highest player is: " + Feb8.highestPlayerInGrade(5));
        System.out.println("Grade 9 highest player is: " + Feb8.highestPlayerInGrade(9));
        System.out.println("Grade 4 highest player is: " + Feb8.highestPlayerInGrade(4));
        System.out.println("Number players with rank between 400 and 700 is: "
                + Feb8.NumberPlayersBetween(400, 700));

        ArrayList<String> highRankPlayers = Feb8.PlayersWithRankGreater(600);
        System.out.println("Name of players rank greater than 600: ");
        for (String name: highRankPlayers)
        {
            System.out.print(name + " ");
        }
    }

    // returns the number of players whose rank is between minRank and maxRank inclusive
    public int NumberPlayersBetween (int minRank, int maxRank)
    {
        // code not shown
    }
}
Here is a sample data file called chessdata.txt.

Narten 680 5
Lapidus 956 5
Ward 550 5
Smith 430 3
Yee 800 4
Parker 0 8
Kumar 0 4
Guilak 758 5

Here is the corresponding output when the program is run with this data file.

Grade 5 highest player is: Lapidus
Grade 9 highest player is: No Player in this grade.
Grade 4 highest player is: Yee
Number players with rank between 400 and 700 is: 3
Name of players rank greater than 600:
Narten Lapidus Yee Guilak

PART B1 (6 pts):
Note that the Scanner input is already bound to a file in main. The file is in the following format. Each line in the file has the name of a player (containing no blanks), the rank of the player as an integer and the grade of a player as an integer.
Complete the constructor for the ChessTournament class below. (hint: what do you need to construct with new?)

    public ChessTournament (Scanner input)
    {
    }
PART B2 (6 pts):
Complete the method \textit{NumberPlayersBetween} that has two parameters \textit{minRank} and \textit{maxRank} and returns the number of players whose rank is between \textit{minRank} and \textit{maxRank} inclusive.

For the example shown earlier in which Feb8 is a ChessTournament variable, the call \textit{Feb8.NumberPlayersBetween(400, 700)} returned 3.

\[
\text{// returns the number of players whose rank is between minRank and maxRank inclusive}
\]

\[
\text{public int NumberPlayersBetween (int minRank, int maxRank)}
\]

\[
\{
\}
\]

PART B3 (6 pts):
Complete the method \textit{highestPlayerInGrade} that has a grade as a parameter and returns the name of the highest ranking player in that grade, or returns the string “No Player in this grade” if there are no players in that grade.

See the three examples earlier for grade 5 (Lapidus), grade 9 (No player in this grade) and grade 3 (Yee).

\[
\text{// returns the name of the highest ranking player in the given grade}
\]

\[
\text{public String highestPlayerInGrade(int grade)}
\]

\[
\{
\}
\]

PART B4 (6 pts):
Complete the method \textit{PlayersWithRankGreater} that has one parameter, a rank, and returns an ArrayList of names of players with that rank.

See the previous example in which Feb8 is a ChessTournament object tied to the given data file and the call \textit{Feb8.PlayersWithRankGreater(600)} returned an ArrayList with the names of the 4 players whose rank is greater than 600 (Narten Lapidus Yee Guilak).

\[
\text{// returns an ArrayList of names of players whose rank is greater than rank}
\]

\[
\text{public ArrayList<String> PlayersWithRankGreater(int rank)}
\]

\[
\{
\}
\]

\[
\text{public class String}
\]

\[
\{
\text{// Returns the length of this string.}
\}
\]
public int length ()

// Returns a substring of this string that begins at the specified
// beginIndex and extends to the character at index endIndex - 1.
public String substring (int beginIndex, int endIndex)

// Returns a substring of this string that begins at the specified
// beginIndex and extends to the end of the string.
public String substring (int beginIndex)

// Returns position of the first occurrence of str, returns -1 if not found
public int indexOf (String str)

// Returns the position of the first occurrence of str after index start
// returns -1 if str is not found
public int indexOf (String str, int start)

// returns character at position index
public char charAt(int index)

// returns true if str has the exact same characters in the same order
public boolean equals(String str)

// returns the string as an array of characters
public char [] toCharArray()

public class ArrayList
{
    // Constructs an empty list
    public ArrayList ()

    // Returns the number of elements in this list.
    public int size ()

    // Returns element at position index in this list.
    public Object get (int index)

    // Replaces the item at position index with element.
    public Object set (int index, Object element)

    // Appends specified element to end of this list.
    public boolean add (Object o)
}

public class Scanner
public Scanner (File file)

public Scanner (String str)

public void useDelimiter (String characters)

public boolean hasNext ()

public String next ()

public String nextLine ()

public int nextInt ()

public double nextDouble ()
