Physical Data Organization

CPS 116
Introduction to Database Systems

Announcements (Tue. Nov. 15)
- Homework #3 sample solution available
- Homework #4 will not be officially assigned until next Tuesday
  - But you can already start with 4.1 on Gradiance

Outline
- It's all about disks!
  - That's why we always draw databases as
  - And why the single most important metric in database processing is (oftentimes) the number of disk I/O's performed
- Storing data on a disk
  - Record layout
  - Block layout

Storage hierarchy

How far away is data?

<table>
<thead>
<tr>
<th>Location</th>
<th>Cycles</th>
<th>Location</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registers</td>
<td>1</td>
<td>My head</td>
<td>1 min.</td>

* I/O dominates—design your algorithms to reduce I/O!*

A typical disk

*Moving parts* are slow

Arm movement Spindle rotation

Tracks Platter

Platter

Cylinders

Disk arm
Top view

“Zoning”: more sectors/data on outer tracks

Disk access time

Sum of:
- Seek time: time for disk heads to move to the correct cylinder
- Rotational delay: time for the desired block to rotate under the disk head
- Transfer time: time to read/write data in the block

Random disk access

Seek time + rotational delay + transfer time
- Average seek time
  - Time to skip one half of the cylinders?
  - Not quite; should be time to skip a third of them (why?)
  - “Typical” value: 5 ms
- Average rotational delay
  - Time for a half rotation (a function of RPM)
  - “Typical” value: 4.2 ms (7200 RPM)

Sequential disk access

Seek time + rotational delay + transfer time
- Seek time
  - 0 (assuming data is on the same track)
- Rotational delay
  - 0 (assuming data is in the next block on the track)
- Easily an order of magnitude faster than random disk access!

Performance tricks

- Disk layout strategy
  - Keep related things (what are they?) close together: same sector/block → same track → same cylinder → adjacent cylinder
- Double buffering
  - While processing the current block in memory, prefetch the next block from disk (overlap I/O with processing)
- Disk scheduling algorithm
  - Example: “elevator” algorithm
- Track buffer
  - Read/write one entire track at a time
- Parallel I/O
  - More disk heads working at the same time

Record layout

Record = row in a table
- Variable-format records
  - Rare in DBMS—table schema dictates the format
  - Relevant for semi-structured data such as XML
- Focus on fixed-format records
  - With fixed-length fields only, or
  - With possible variable-length fields
Fixed-length fields

- All field lengths and offsets are constant
  - Computed from schema, stored in the system catalog
- Example: CREATE TABLE Student(SID INT, name CHAR(20), age INT, GPA FLOAT);

<table>
<thead>
<tr>
<th>0</th>
<th>4</th>
<th>8</th>
<th>12</th>
<th>16</th>
<th>20</th>
<th>24</th>
<th>28</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>142</td>
<td>Bart (padded with space)</td>
<td>10</td>
<td>2.3</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Watch out for alignment
  - May need to pad; reorder columns if that helps
- What about NULL?
  - Add a bitmap at the beginning of the record

Variable-length records

- Example: CREATE TABLE Student(SID INT, name VARCHAR(20), age INT, GPA FLOAT, comment VARCHAR(100));
- Approach 1: use field delimiters ("\0" okay?)
<table>
<thead>
<tr>
<th>0</th>
<th>4</th>
<th>8</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>142</td>
<td>10</td>
<td>2.3</td>
<td>Bart\0 Weird kid\0</td>
</tr>
</tbody>
</table>
- Approach 2: use an offset array
<table>
<thead>
<tr>
<th>0</th>
<th>4</th>
<th>8</th>
<th>16</th>
<th>18</th>
<th>22</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>142</td>
<td>10</td>
<td>2.3</td>
<td>Bart</td>
<td>Weird kid\0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Put all variable-length fields at the end (why?)
- Update is messy if it changes the length of a field

LOB fields

- Example: CREATE TABLE Student(SID INT, name CHAR(20), age INT, GPA FLOAT, picture BLOB(32000));
- Student records get “de-clustered”
  - Bad because most queries do not involve picture
- Decomposition (automatically done by DBMS and transparent to the user)
  - Student(SID, name, age, GPA)
  - StudentPicture(SID, picture)

Block layout

How do you organize records in a block?

- NSM (N-ary Storage Model)
  - Most commercial DBMS
- PAX (Partition Attributes Across)
  - Ailamaki et al., VLDB 2001

NSM

- Store records from the beginning of each block
- Use a directory at the end of each block
  - To locate records and manage free space
  - Necessary for variable-length records

<table>
<thead>
<tr>
<th>0</th>
<th>4</th>
<th>8</th>
<th>12</th>
<th>16</th>
<th>20</th>
<th>24</th>
<th>28</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>142</td>
<td>Bart</td>
<td>10</td>
<td>2.3</td>
<td>Milhouse</td>
<td>10</td>
<td>3.1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Why store data and directory at two different ends?
Both can grow easily

Options

- Reorganize after every update/delete to avoid fragmentation (gaps between records)
  - Need to rewrite half of the block on average
- What if records are fixed-length?
  - Reorganize after delete
    - Only need to move one record
    - Need a pointer to the beginning of free space
  - Do not reorganize after update
    - Need a bitmap indicating which slots are in use
Cache behavior of NSM

- Query: SELECT SID FROM Student WHERE GPA > 2.0;
- Assumption: cache line size < record size
- Lots of cache misses
  - SID and GPA are not close enough by memory standards

![Diagram of cache behavior]

PAX

- Most queries only access a few columns
- Cluster values of the same columns in each block
  - When a particular column of a row is brought into the cache, the same column of the next row is brought in together

![Diagram of PAX]

Summary

- Storage hierarchy
  - Why I/O’s dominate the cost of database operations
- Disk
  - Steps in completing a disk access
  - Sequential versus random accesses
- Record layout
  - Handling variable-length fields
  - Handling NULL
  - Handling modifications
- Block layout
  - NSM: the traditional layout
  - PAX: a layout that tries to improve cache performance
