SAX and DOM

Introduction to Databases
CompSci 316 Fall 2014
Announcements (Tue., Nov. 4)

- Homework #3 due Thursday
- Project milestone #2 due next Thursday
SAX & DOM

Both are API’s for XML processing

- **SAX (Simple API for XML)**
  - Started out as a Java API, but now exists for other languages too

- **DOM (Document Object Model)**
  - Language-neutral API with implementations in Java, C++, python, etc.
SAX processing model

• Serial access
  • XML document is processed as a stream
  • Only one look at the data
  • Cannot go back to an early portion of the document

• Event-driven
  • A parser generates **events** as it goes through the document (e.g., start of the document, end of an element, etc.)
  • Application defines **event handlers** that get invoked when events are generated
SAX events

Most frequently used events:

- **startDocument**
- **endDocument**
- **startElement**
- **endElement**
- **characters**

  - Whenever the parser has processed a chunk of character data (without generating other kinds of events)
  - Warning: The parser may generate multiple characters events for one piece of text

Whitespace may come up as characters or ignorableWhitespace, depending on whether a DTD is present.
A simple SAX example

• Print out text contents of title elements

```python
import sys
import xml.sax
from StringIO import StringIO

class PathHandler(xml.sax.ContentHandler):
    def startDocument(self):
        ...
    def startElement(self, name, attrs):
        ...
        
xml.sax.parse(sys.stdin, PathHandler())
```
A simple SAX example (cont’d)

```python
def startDocument(self):
    self.outBuffer = None

def startElement(self, name, attrs):
    if name == 'title':
        self.outBuffer = StringIO()

def endElement(self, name):
    if name == 'title':
        print self.outBuffer.getvalue()
        self.outBuffer = None

def characters(self, content):
    if self.outBuffer is not None:
        self.outBuffer.write(content)
```

Tag name

A map from attribute names to values

Characters read
A common mistake

What is wrong with the following?

```python
def endElement(self, name):
    # print the last chunk of chars before </title>:
    if name == 'title':
        print self.chars

def characters(self, content):
    self.chars = content
```

- Cannot handle the case where other tags appear within a `title` element
- It is possible that `characters()` are called multiple times for one piece of text; this code only prints out the last part
A more complex SAX example

• Print out the text contents of top-level section titles in books, i.e., //book/section/title
  • Old code would print out all titles, e.g., //book/title, //book//section/title
  • For simplicity, assume that if we have the pattern //book/section/title//book/section/title, we print the higher-level title element

• Idea:

```python
def startDocument(self):
    self.path = list()
    self.pathLenWhenOutputStarts = None
    self.outBuffer = None
```
A more complex SAX example (cont’d)

def startElement(self, name, attrs):
    self.path.append(name)  # maintain the path
    if len(self.path) >= 3 and \
        self.path[-3:] == ['book', 'section', 'title']:
        # path matches //book/section/title:
        if self.outBuffer is None:
            self.pathLenWhenOutputStarts = len(self.path)
            self.outBuffer = StringIO()

def endElement(self, name):
    if self.outBuffer is not None and \
        len(self.path) == self.pathLenWhenOutputStarts:
        print self.outBuffer.getvalue()
        self.outBuffer = None
    self.path.pop()  # maintain the path

def characters(self, content):
    if self.outBuffer is not None:
        self.outBuffer.write(content)

Would it work if we change this check to name == "title"?
Would it work if we remove this check?
DOM processing model

• XML is parsed by a parser and converted into an in-memory DOM tree

• DOM API allows an application to
  • Construct a DOM tree from an XML document
  • Traverse and read a DOM tree
  • Construct a new, empty DOM tree from scratch
  • Modify an existing DOM tree
  • Copy subtrees from one DOM tree to another etc.
DOM Node’s

• A DOM tree is made up of Node’s

• Most frequently used types of Node’s:
  • **Document**: root of the DOM tree
    • Not the same as the root element of XML
  • **DocumentType**: corresponds to the DOCTYPE declaration in an XML document
  • **Element**: corresponds to an XML element
  • **Attr**: corresponds to an attribute of an XML element
  • **Text**: corresponds to chunk of text
DOM example

<?xml version="1.0"?>
<!DOCTYPE ...
<bibliography>
  <book ISBN="ISBN-10" price="80.00">
    <title>Foundations of Databases</title>
    <author>Abiteboul</author>
    <author>Hull</author>
    <author>Vianu</author>
  </book>
  ...
</bibliography>

Whitespace in between elements is also parsed as Text (unless DTD or parsing option specify otherwise)
Node interface

\texttt{n.nodeType} returns the type of Node \texttt{n}
\n\texttt{n.childNodes} returns a list containing \texttt{n}'s children
  \begin{itemize}
  \item E.g., subelements are children of an Element; DocumentType is a child of the Document
  \item \texttt{n.appendChild(c)} adds Node \texttt{c} as the last child of \texttt{n}
  \end{itemize}
\n\texttt{d.documentElement} returns the root Element of Document \texttt{d}
\n\texttt{e.nodeName} returns the tag name of Element \texttt{e}
\n\texttt{e.attributes} returns a NamedNodeMap containing \texttt{e}'s attributes
  \begin{itemize}
  \item Attributes are not considered children!
  \item Loop through attributes using
    \begin{verbatim}
    for i in range(e.attributes.length):
      a = e.attributes.item(i)
    \end{verbatim}
    \begin{itemize}
    \item \texttt{a.nodeName} returns the attribute name
    \item \texttt{a.nodeValue} returns the attribute value
    \end{itemize}
  \item Given \texttt{e}, \texttt{e.getAttribute(name)}, \texttt{e.setAttribute(name, value)} are also available
  \end{itemize}
\n\texttt{t.getNodeValue} returns the content of Text \texttt{t}

For convenience: \texttt{n.parentNode}, \texttt{n.previousSibling}, \texttt{n.nextSibling}, \texttt{n.ownerDocument}, etc.
import sys
reload(sys)
sys.setdefaultencoding('utf-8')  # Hack to ensure Unicode I/O
from xml.dom.minidom import parse

dom = parse(sys.stdin)
# now print it back out:
print dom.toprettyxml(indent=' '*4, encoding='utf-8')
Traversing DOM

• Compute the string value of an XML node

```python
def nodeToString(n):
    # string value of a Text node is just its content:
    if n.nodeType == n.TEXT_NODE:
        return n.nodeValue;
    # string value of a Node of another type is the
    # concatenation of its children’s string values:
    return ' '.join(
        nodeToString(child)
        for child in n.childNodes
    )
```
Traversing DOM

- Print out text contents of title elements

```python
def outputTitle(n):
    if n.nodeType == n.ELEMENT_NODE and
        n.nodeName == 'title':
        print nodeToString(n);
    else:
        for child in n.childNodes:
            outputTitle(child)
```

- How do you print out just //book/section/title?
  - Use parentNode to check for section parent and book grandparent
Constructing DOM from scratch

• Construct a DOM Document showing all titles as follows:
  
  ```xml
  <result>
    <title text="title1"/>
    <title text="title2"/>
    ...
  </result>
  ```

```python
from xml.dom.minidom import getDOMImplementation

def addTitles(n, newdoc):
    if n.nodeType == input.ELEMENT_NODE and n.nodeName == 'title':
        e = newdoc.createElement('result')
        e.setAttribute('text', nodeToString(n))
        newdoc.documentElement.appendChild(e)
    else:
        for child in n.childNodes:
            addTitles(child, newdoc)

newdom = getDOMImplementation().createDocument(None, 'result', None)
addTitles(dom, newdom)
```
Copying subtrees in DOM

• Construct a DOM Document showing all title elements from the input XML

```python
from xml.dom.minidom import getDOMImplementation

def addTitles2(n, newdoc):
    if n.nodeType == input.ELEMENT_NODE and n.nodeName == 'title':
        e = newdoc.importNode(n, True)
        newdoc.documentElement.appendChild(e)
    else:
        for child in n.childNodes:
            addTitles2(child, newdoc)

newdom = getDOMImplementation().createDocument(None, 'result', None)
addTitles2(dom, newdom)
```

A Document can import (copy) a Node from another element; the second argument specifies whether to copy recursively or not.
Summary: SAX versus DOM

• SAX
  • Because of one-pass processing, a SAX parser is fast, consumes very little memory
  • Applications are responsible for keeping necessary state in memory, and are therefore more difficult to code

• DOM
  • Because the input XML needs to be converted to an in-memory DOM-tree representation, a DOM parser consumes more memory
    • Lazy materialization of DOM tree helps alleviate this problem
  • Applications are easier to develop because of the powerful DOM interface

• Which one scales better for huge XML input?
