Introduction to Databases
CompSci 316 Fall 2015
Outline

• It’s all about disks!
  • That’s why we always draw databases as
  • And why the single most important metric in database processing is (oftentimes) the number of disk I/O’s performed

• Storing data on a disk
  • Record layout
  • Block layout
Storage hierarchy

Why a hierarchy?
How far away is data?

The gap has been widening!

全日 I/O dominates—design your algorithms to reduce I/O!
A typical hard drive

A typical hard drive

“Moving parts” are slow
Top view

“Zoning”: more sectors/data on outer tracks

A block is a logical unit of transfer consisting of one or more sectors
Disk access time

Sum of:

- **Seek time**: time for disk heads to move to the correct cylinder
- **Rotational delay**: time for the desired block to rotate under the disk head
- **Transfer time**: time to read/write data in the block (= time for disk to rotate over the block)
Random disk access

Seek time + rotational delay + transfer time

- Average seek time
  - Time to skip one half of the cylinders?
    - “Typical” value: 5 ms

- Average rotational delay
  - “Typical” value: 4.2 ms (7200 RPM)
Sequential disk access

Seek time + rotational delay + transfer time

• Seek time
  • 0 (assuming data is on the same track)

• Rotational delay
  • 0 (assuming data is in the next block on the track)

• Easily an order of magnitude faster than random disk access!
What about SSD (solid-state drives)?
What about SSD (solid-state drives)?

• No mechanical parts
• Mostly flash-based nowadays
• 1-2 orders of magnitude faster random access than hard drives (under 0.1ms vs. several ms)
  • But still much slower than memory (~0.1μs)
• Little difference between random vs. sequential read performance
• Random writes still hurt
  • In-place update would require erasing the whole “erasure block” and rewriting it!
Important consequences

• It’s all about reducing I/O’s!
• Cache blocks from stable storage in memory
  • DBMS maintains a memory buffer pool of blocks
  • Reads/writes operate on these memory blocks
  • Dirty (updated) memory blocks are “flushed” back to stable storage
• Sequential I/O is much faster than random I/O
Performance tricks

• Disk layout strategy
  • Keep related things (what are they?) close together: same sector/block → same track → same cylinder → adjacent cylinder

• Prefetching
  • While processing the current block in memory, fetch the next block from disk (overlap I/O with processing)

• Parallel I/O
  • More disk heads working at the same time

• Disk scheduling algorithm
  • Example: “elevator” algorithm

• Track buffer
  • Read/write one entire track at a time
Record layout

Record = row in a table

• Variable-format records
  • Rare in DBMS—table schema dictates the format
  • Relevant for semi-structured data such as XML

• Focus on fixed-format records
  • With fixed-length fields only, or
  • With possible variable-length fields
Fixed-length fields

• All field lengths and offsets are constant
  • Computed from schema, stored in the system catalog

• Example: CREATE TABLE User(uid INT, name CHAR(20), age INT, pop FLOAT);

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th>24</th>
<th>28</th>
<th>36</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td></td>
<td>142</td>
<td>Bart (padded with space)</td>
<td>10</td>
</tr>
</tbody>
</table>

• Watch out for alignment
  • May need to pad; reorder columns if that helps

• What about NULL?
Variable-length records

• Example: `CREATE TABLE User(uid INT, name VARCHAR(20), age INT, pop FLOAT, comment VARCHAR(100));`

• Approach 1: use field delimiters (‘\0’ okay?)

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>8</td>
<td>16</td>
</tr>
<tr>
<td>142</td>
<td>10</td>
<td>0.9</td>
<td>Bart\0</td>
</tr>
</tbody>
</table>

• Approach 2: use an offset array

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>8</td>
<td>16</td>
<td>18</td>
</tr>
<tr>
<td>142</td>
<td>10</td>
<td>0.9</td>
<td>Bart</td>
<td>Weird kid!</td>
</tr>
</tbody>
</table>

• Put all variable-length fields at the end (why?)
• Update is messy if it changes the length of a field
LOB fields

• Example: CREATE TABLE User(
  uid INT,
  name CHAR(20), age INT,
  pop FLOAT, picture BLOB(32000));
Block layout

How do you organize records in a block?

- **NSM** (N-ary Storage Model)
  - Most commercial DBMS
- **PAX** (Partition Attributes Across)
  - Ailamaki et al., VLDB 2001
NSM

• Store records from the beginning of each block
• Use a directory at the end of each block
  • To locate records and manage free space
  • Necessary for variable-length records

Why store data and directory at two different ends?
Options

• Reorganize after every update/delete to avoid fragmentation (gaps between records)
  • Need to rewrite half of the block on average

• A special case: What if records are fixed-length?
  • Option 1: reorganize after delete
    • Only need to move one record
    • Need a pointer to the beginning of free space
  • Option 2: do not reorganize after update
    • Need a bitmap indicating which slots are in use
Cache behavior of NSM

- **Query**: `SELECT uid FROM User WHERE pop > 0.8;
- **Assumptions**: no index, and cache line size < record size
- **Lots of cache misses**
  - `uid` and `pop` are not close enough by memory standards

![Cache diagram]
PAX

- Most queries only access a few columns
- Cluster values of the same columns in each block
  - When a particular column of a row is brought into the cache, the same column of the next row is brought in together

Reorganize after every update (for variable-length records only) and delete to keep fields together

(number of records)

(IS NOT NULL bitmap)
Beyond block layout: column stores

• The other extreme: store tables by columns instead of rows

• Advantages (and disadvantages) of PAX are magnified
  • Not only better cache performance, but also fewer I/O’s for queries involving many rows but few columns
  • Aggressive compression to further reduce I/O’s

• More disruptive changes to the DBMS architecture are required than PAX
  • Not only storage, but also query execution and optimization
