SQL: Recursion

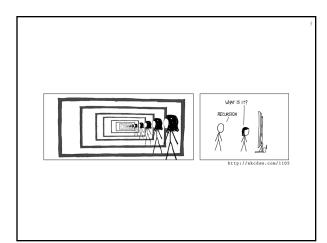

CompSci 316 Fall 2016

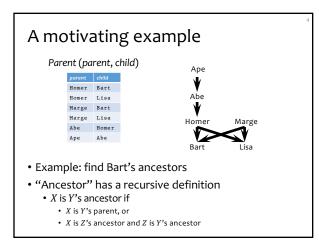

Announcements (Tue., Sep. 29)

- Homework #2 due tonight
 Deadline extended to Thursday for Problem 6
- (Gradiance) and Problem X₂ (non-Gradiance) • Midterm in class Thursday
 - Open-book, open-notes

DUKE COMPUTER SCIENCE

- Same format as sample midterm (from last year)
 Sample solution also posted in Sakai
- Project Milestone #1 due next Thursday

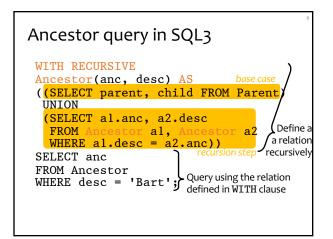

- SQL2 had no recursion
 - You can find Bart's parents, grandparents, great grandparents, etc.
 - SELECT pl.parent AS grandparent FROM Parent pl, Parent p2 WHERE pl.child = p2.parent AND p2.child = 'Bart';

 - But you cannot find all his ancestors with a single query
- SQL3 introduces recursion
 - WITH clause
 - Implemented in PostgreSQL (common table expressions)

Fixed point of a function

- If $f: T \to T$ is a function from a type T to itself, a fixed point of f is a value x such that f(x) = x
- Example: What is the fixed point of *f*(*x*) = *x*/2?
 0, because *f*(0) = 0/2 = 0
- To compute a fixed point of *f*
 - Start with a "seed": $x \leftarrow x_0$
 - Compute f(x)
 - If f(x) = x, stop; x is fixed point of f
 Otherwise, x ← f(x); repeat
 - Otherwise, $x \leftarrow f(x)$, repeat
- Example: compute the fixed point of f(x) = x/2
 With seed 1: 1, 1/2, 1/4, 1/8, 1/16, ... → 0
- [@]Doesn't always work, but happens to work for us!
- Fixed point of a query
- A query q is just a function that maps an input table to an output table, so a fixed point of q is a table T such that q(T) = T
- To compute fixed point of *q*
 - Start with an empty table: $T \leftarrow \emptyset$
 - Evaluate q over \dot{T}
 - If the result is identical to T, stop; T is a fixed point
 - Otherwise, let T be the new result; repeat
 - Starting from Ø produces the unique minimal fixed point (assuming q is monotone)

Intuition behind fixed-point iteration

- Initially, we know nothing about ancestordescendent relationships
- In the first step, we deduce that parents and children form ancestor-descendent relationships
- In each subsequent steps, we use the facts deduced in previous steps to get more ancestor-descendent relationships
- We stop when no new facts can be proven

Linear recursion

• With linear recursion, a recursive definition can make only one reference to itself

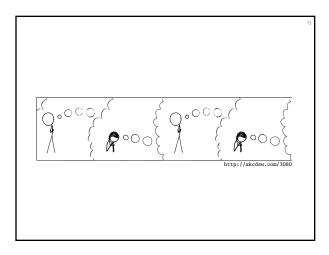

- Non-linear
 - WITH RECURSIVE Ancestor(anc, desc) AS ((SELECT parent, child FROM Parent) UNION (SELECT al.anc, a2.desc
 - FROM Ancestor al, Ancestor a2 WHERE al.desc = a2.anc))
- Linear

• WITH RECURSIVE Ancestor(anc, desc) AS ((SELECT parent, child FROM Parent) UNION (SELECT anc, child FROM Ancestor, Parent WHERE desc = parent))

Linear vs. non-linear recursion

• Linear recursion is easier to implement

- For linear recursion, just keep joining newly generated Ancestor rows with Parent
- For non-linear recursion, need to join newly generated Ancestor rows with all existing Ancestor rows
- Non-linear recursion may take fewer steps to converge, but perform more work
 - Example: $a \rightarrow b \rightarrow c \rightarrow d \rightarrow e$
 - Linear recursion takes 4 steps
 - Non-linear recursion takes 3 steps
 - More work: e.g., $a \rightarrow d$ has two different derivations

Mutual recursion example

• Table Natural (n) contains 1, 2, ..., 100

- Which numbers are even/odd?
 - An odd number plus 1 is an even number
 - An even number plus 1 is an odd number

• 1 is an odd number

WITH RECURSIVE Even(n) AS
 (SELECT n FROM Natural
 WHERE n = ANY(SELECT n+1 FROM Odd)),
 RECURSIVE Odd(n) AS
 ((SELECT n FROM Natural WHERE n = 1)
 UNION

(SELECT n FROM Natural WHERE n = ANY(SELECT n+1 FROM Even)))

Semantics of WITH

```
• WITH RECURSIVE R_1 AS Q_1, ...,

RECURSIVE R_n AS Q_n

Q_i;

• Q and Q_1, ..., Q_n may refer to R_1, ..., R_n

• Semantics

1. R_1 \leftarrow \emptyset, ..., R_n \leftarrow \emptyset

2. Evaluate Q_1, ..., Q_n using the current contents of R_1, ..., R_n:

R_1^{new} \leftarrow Q_1, ..., R_n^{new} \leftarrow Q_n

3. If R_i^{new} \neq R_i for some i

3.1. R_1 \leftarrow R_1^{new}, ..., R_n \leftarrow R_n^{new}

3.2. Go to 2.

4. Compute Q using the current contents of R_1, ..., R_n

and output the result
```

Computing mutual recursion

```
WITH RECURSIVE Even(n) AS
(SELECT n FROM Natural
WHERE n = ANY(SELECT n+1 FROM Odd)),
MIGSL H = ANI(SELECT N+1 FROM Odd)),
RECURSIVE Odd(n) AS
((SELECT n FROM Natural WHERE n = 1)
UNION
(SELECT n FROM Natural
WHERE n = ANY(SELECT n+1 FROM Even)))
• Even = Ø, Odd = Ø
• Even = Ø, Odd = {1}
• Even = {2}, Odd = {1}
• Even = {2}, Odd = {1, 3}
• Even = {2, 4}, Odd = {1, 3}
• Even = {2, 4}, Odd = {1, 3, 5}
• ....
```

| | | | | | 17 | |
|--|--------|-----------|----------|-------|----|--|
| Fixed points are no | ot u | nique | 2 anc | desc | | |
| • | | <u> </u> | Homer | Bart | i | |
| WITH RECURSIVE | parent | child | Homer | Lisa | | |
| Ancestor(anc, desc) AS ((SELECT parent, child FROM Parent) UNION (SELECT al.anc, a2.desc FROM Ancestor al, Ancestor a2 WHERE al.desc = a2.anc)) | Homer | Bart | Marge | Bart | | |
| | Homer | Lisa | Marge | Lisa | | |
| | Marge | Bart | Abe | Homer | | |

| Noteho | | ogus tupl | | Bogus | | |
| But if q is monotone, then all these fixed points must contain the fixed point we computed from fixed-point iteration starting with Ø Thus the unique minimal fixed point is the "natural" answer | | | | | | |

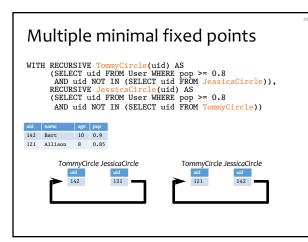

Mixing negation with recursion

- If *q* is non-monotone
 - The fixed-point iteration may flip-flop and never converge • There could be multiple minimal fixed points—we wouldn't know which one to pick as answer!
- Example: popular users (pop \ge 0.8) join either Jessica's Circle or Tommy's
 - Those not in Jessica's Circle should be in Tom's

 - Those not in Tom's Circle should be in Jessica's
 - THOSE HOLEN TOTILS CHICKE SHOULD DE HIJESSICA S
 WITH RECURSIVE TommyCircle(uid) AS (SELECT uid FROM User WHERE pop >= 0.8 AND uid NOT IN (SELECT uid FROM JessicaCircle)), RECURSIVE JessicaCircle(uid) AS (SELECT uid FROM User WHERE pop >= 0.8 AND uid NOT IN (SELECT uid FROM TommyCircle))

Fixed-point iter may not converge WITH RECURSIVE TommyCircle(uid) AS (SELECT uid FROM User WHERE pop >= 0.8 AND uid NOT IN (SELECT uid FROM JessicaCircle)), RECURSIVE JessicaCircle(uid) AS (SELECT uid FROM User WHERE pop >= 0.8 AND uid NOT IN (SELECT uid FROM TommyCircle)) wdd mome version ver

Stratified negation example

| • Find pairs of persons with no common a | ancestors | | | |
|--|-----------|--|--|--|
| <pre>WITH RECURSIVE Ancestor(anc, desc) AS ((SELECT parent, child FROM Parent) UNION (SELECT al.anc, a2.desc FROM Ancestor al, Ancestor a2 WHERE al.desc = a2.anc)),</pre> | | | | |
| Person(person) AS ((SELECT parent FROM Parent) UNION (SELECT child FROM Parent)), | Ancestor | | | |
| NoCommonAnc(personl, person2) AS ((SELECT pl.person, p2.person FROM Person pl, Person p2 | Person | | | |
| WHERE pl.person <> p2.person) EXCEPT (SELECT al.desc, a2.desc FROM Ancestor al, Ancestor a2 WHERE al.anc = a2.anc)) | | | | |
| SELECT * FROM NoCommonAnc; | | | | |

Evaluating stratified negation

• The stratum of a node *R* is the maximum number of "-" edges on any path from *R* in the dependency graph

Person

NoCommonAnc

- in the dependency graph
- Ancestor: stratum o
- Person: stratum 0
- NoCommonAnc: stratum 1
- Evaluation strategy
 - Compute tables lowest-stratum first
 - For each stratum, use fixed-point iteration on all nodes in that stratum
 - Stratum o: Ancestor and Person
 - Stratum 1: NoCommonAnc
 - Thruitively, there is no negation within each stratum

Summary

- SQL3 WITH recursive queries
- Solution to a recursive query (with no negation): unique minimal fixed point
- Computing unique minimal fixed point: fixed-point iteration starting from $\ensuremath{\varnothing}$
- Mixing negation and recursion is tricky
 - Illegal mix: fixed-point iteration may not converge; there may be multiple minimal fixed points
 - Legal mix: stratified negation (compute by fixed-point iteration stratum by stratum)
