# SQL: Recursion

Introduction to Databases

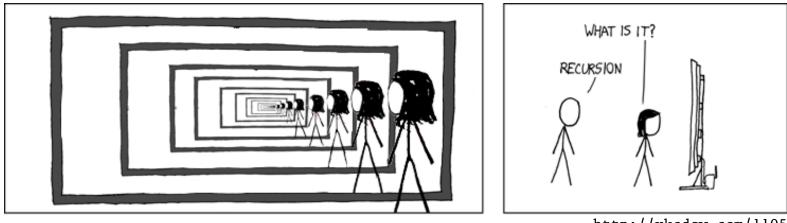

CompSci 316 Fall 2016

# Announcements (Tue., Sep. 29)

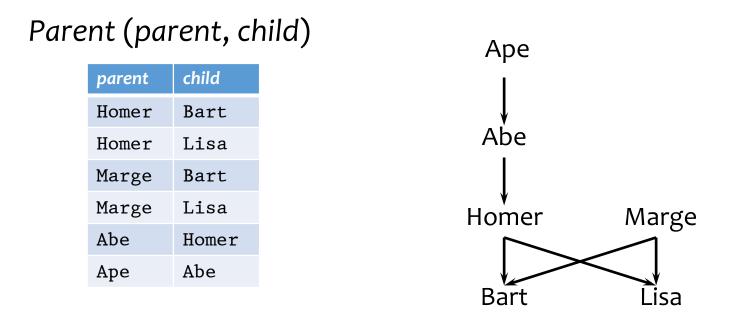

#### Homework #2 due tonight

- Deadline extended to Thursday for Problem 6 (Gradiance) and Problem X2 (non-Gradiance)
- Midterm in class Thursday
  - Open-book, open-notes
  - Same format as sample midterm (from last year)
    - Sample solution also posted in Sakai
- Project Milestone #1 due next Thursday

http://xkcdsw.com/1105

# A motivating example

- Example: find Bart's ancestors
- "Ancestor" has a recursive definition
  - X is Y's ancestor if
    - X is Y's parent, or
    - X is Z's ancestor and Z is Y's ancestor

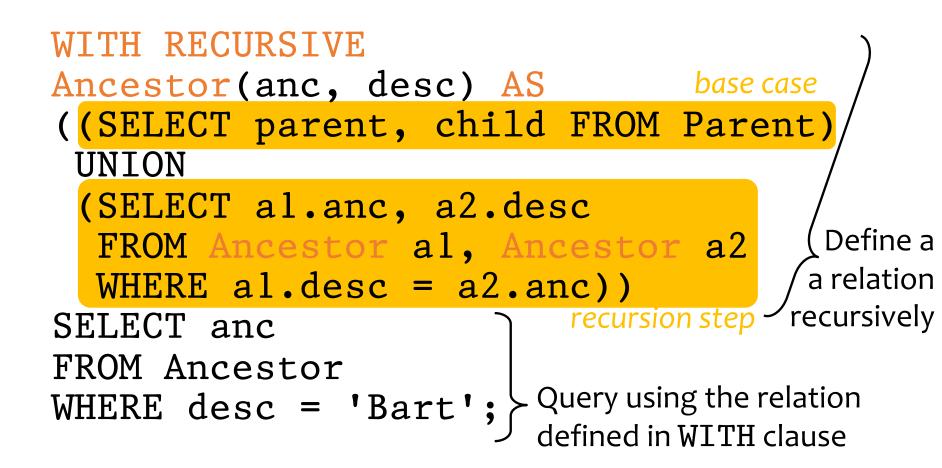

# **Recursion in SQL**

- SQL2 had no recursion
  - You can find Bart's parents, grandparents, great grandparents, etc.

SELECT pl.parent AS grandparent
FROM Parent pl, Parent p2
WHERE pl.child = p2.parent
AND p2.child = 'Bart';

- But you cannot find all his ancestors with a single query
- SQL3 introduces recursion
  - WITH clause
  - Implemented in PostgreSQL (common table expressions)

#### Ancestor query in SQL3

#### Fixed point of a function

- If  $f: T \to T$  is a function from a type T to itself, a fixed point of f is a value x such that f(x) = x
- Example: What is the fixed point of f(x) = x/2?
  - 0, because f(0) = 0/2 = 0
- To compute a fixed point of f
  - Start with a "seed":  $x \leftarrow x_0$
  - Compute f(x)
    - If f(x) = x, stop; x is fixed point of f
    - Otherwise,  $x \leftarrow f(x)$ ; repeat
- Example: compute the fixed point of f(x) = x/2
  - With seed 1: 1, 1/2, 1/4, 1/8, 1/16, ...  $\rightarrow 0$

Doesn't always work, but happens to work for us!

# Fixed point of a query

- A query q is just a function that maps an input table to an output table, so a fixed point of q is a table T such that q(T) = T
- To compute fixed point of  $\boldsymbol{q}$ 
  - Start with an empty table:  $T \leftarrow \emptyset$
  - Evaluate q over T
    - If the result is identical to *T*, stop; *T* is a fixed point
    - Otherwise, let *T* be the new result; repeat
  - Starting from Ø produces the unique minimal fixed point (assuming q is monotone)

# Finding ancestors

•	WITH RECURSIVE
	Ancestor(anc, desc) AS
	((SELECT parent, child FROM Parent)
	UNION
	(SELECT al.anc, a2.desc
	FROM Ancestor al, Ancestor a2
	WHERE al.desc = a2.anc))

• Think of the definition as Ancestor = q(Ancestor)

parent	child
Homer	Bart
Homer	Lisa
Marge	Bart
Marge	Lisa
Abe	Homer
Аре	Abe

			anc	desc	Homer	Lisa
	anc	desc	Homer	Bart	Marge	Bart
	Homer	Bart	Homer	Lisa	Marge	Lisa
anc desc	Homer	Lisa	Marge	Bart	Abe	Homer
anc desc	Marge	Bart	Marge	Lisa	Аре	Abe
	Marge	Lisa	Abe	Homer	Abe	Bart
	Abe	Homer	Аре	Abe	Abe	Lisa
	Аре	Abe	Abe	Bart	Аре	Homer
			Abe	Lisa	Аре	Bart
			Аре	Homer	Аре	Lisa

desc

Bart

anc

Homer

#### Intuition behind fixed-point iteration

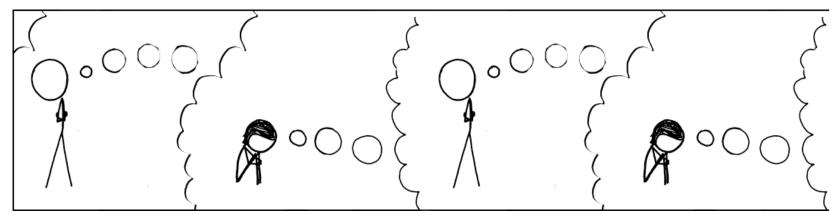

- Initially, we know nothing about ancestordescendent relationships
- In the first step, we deduce that parents and children form ancestor-descendent relationships
- In each subsequent steps, we use the facts deduced in previous steps to get more ancestordescendent relationships
- We stop when no new facts can be proven

#### Linear recursion

- With linear recursion, a recursive definition can make only one reference to itself
- Non-linear
  - WITH RECURSIVE Ancestor(anc, desc) AS ((SELECT parent, child FROM Parent) UNION (SELECT al.anc, a2.desc FROM Ancestor al, Ancestor a2 WHERE al.desc = a2.anc))
- Linear
  - WITH RECURSIVE Ancestor(anc, desc) AS
     ((SELECT parent, child FROM Parent)
     UNION
     (SELECT anc, child
     FROM Ancestor, Parent
     WHERE desc = parent))

#### Linear vs. non-linear recursion

- Linear recursion is easier to implement
  - For linear recursion, just keep joining newly generated Ancestor rows with Parent
  - For non-linear recursion, need to join newly generated Ancestor rows with all existing Ancestor rows
- Non-linear recursion may take fewer steps to converge, but perform more work
  - Example:  $a \rightarrow b \rightarrow c \rightarrow d \rightarrow e$
  - Linear recursion takes 4 steps
  - Non-linear recursion takes 3 steps
    - More work: e.g.,  $a \rightarrow d$  has two different derivations

http://xkcdsw.com/3080

#### Mutual recursion example

- Table Natural (n) contains 1, 2, ..., 100
- Which numbers are even/odd?
  - An odd number plus 1 is an even number
  - An even number plus 1 is an odd number
  - 1 is an odd number

```
WITH RECURSIVE Even(n) AS
  (SELECT n FROM Natural
   WHERE n = ANY(SELECT n+1 FROM Odd)),
   RECURSIVE Odd(n) AS
  ((SELECT n FROM Natural WHERE n = 1)
   UNION
   (SELECT n FROM Natural
   WHERE n = ANY(SELECT n+1 FROM Even)))
```

#### Semantics of WITH

- WITH RECURSIVE  $R_1$  AS  $Q_1$ , ..., RECURSIVE  $R_n$  AS  $Q_n$ 
  - *Q*;
    - Q and  $Q_1, \ldots, Q_n$  may refer to  $R_1, \ldots, R_n$
- Semantics
  - 1.  $R_1 \leftarrow \emptyset$ , ...,  $R_n \leftarrow \emptyset$
  - 2. Evaluate  $Q_1, ..., Q_n$  using the current contents of  $R_1, ..., R_n$ :  $R_1^{new} \leftarrow Q_1, ..., R_n^{new} \leftarrow Q_n$ 3. If  $R_i^{new} \neq R_i$  for some i3.1.  $R_1 \leftarrow R_1^{new}, ..., R_n \leftarrow R_n^{new}$ 3.2. Go to 2.
  - 4. Compute Q using the current contents of  $R_1, \dots R_n$ and output the result

### Computing mutual recursion

- Even =  $\emptyset$ , Odd =  $\emptyset$
- $Even = \emptyset, Odd = \{1\}$
- Even =  $\{2\}$ , Odd =  $\{1\}$
- Even = {2}, Odd = {1, 3}
- Even =  $\{2, 4\}$ , Odd =  $\{1, 3\}$
- Even = {2, 4}, Odd = {1, 3, 5}

# Fixed points are not unique

WITH RECURSIVE	
Ancestor(anc, desc) AS	
((SELECT parent, child FROM	
Parent)	
UNION	
(SELECT al.anc, a2.desc	
FROM Ancestor al, Ancestor a	2
WHERE al.desc = a2.anc))	

parent	child
Homer	Bart
Homer	Lisa
Marge	Bart
Marge	Lisa
Abe	Homer
Аре	Abe

anc	desc
Homer	Bart
Homer	Lisa
Marge	Bart
Marge	Lisa
Abe	Homer
Аре	Abe
Abe	Bart
Abe	Lisa
Аре	Homer
Аре	Bart
Аре	Lisa
Bogus	Bogus

Note how the bogus tuple reinforces itself!

- But if q is monotone, then all these fixed points must contain the fixed point we computed from fixed-point iteration starting with Ø
  - Thus the unique minimal fixed point is the "natural" answer

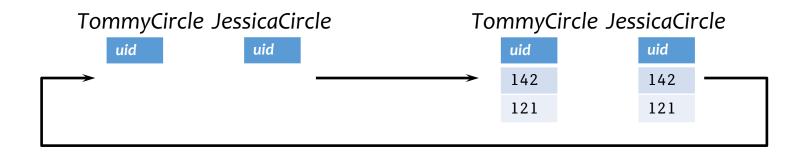

# Mixing negation with recursion

- If *q* is non-monotone
  - The fixed-point iteration may flip-flop and never converge
  - There could be multiple minimal fixed points—we wouldn't know which one to pick as answer!
- Example: popular users (pop ≥ 0.8) join either Jessica's Circle or Tommy's
  - Those not in Jessica's Circle should be in Tom's
  - Those not in Tom's Circle should be in Jessica's
  - WITH RECURSIVE TommyCircle(uid) AS
     (SELECT uid FROM User WHERE pop >= 0.8
     AND uid NOT IN (SELECT uid FROM JessicaCircle)),
     RECURSIVE JessicaCircle(uid) AS
     (SELECT uid FROM User WHERE pop >= 0.8
     AND uid NOT IN (SELECT uid FROM TommyCircle))

#### Fixed-point iter may not converge

WITH RECURSIVE TommyCircle(uid) AS
 (SELECT uid FROM User WHERE pop >= 0.8
 AND uid NOT IN (SELECT uid FROM JessicaCircle)),
 RECURSIVE JessicaCircle(uid) AS
 (SELECT uid FROM User WHERE pop >= 0.8
 AND uid NOT IN (SELECT uid FROM TommyCircle))

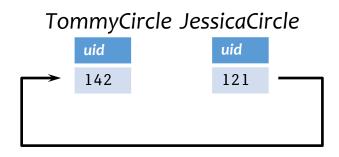

uid	name	age	рор
142	Bart	10	0.9
121	Allison	8	0.85

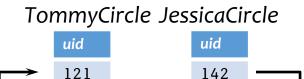

#### Multiple minimal fixed points

WITH RECURSIVE TommyCircle(uid) AS
 (SELECT uid FROM User WHERE pop >= 0.8
 AND uid NOT IN (SELECT uid FROM JessicaCircle)),
 RECURSIVE JessicaCircle(uid) AS
 (SELECT uid FROM User WHERE pop >= 0.8
 AND uid NOT IN (SELECT uid FROM TommyCircle))

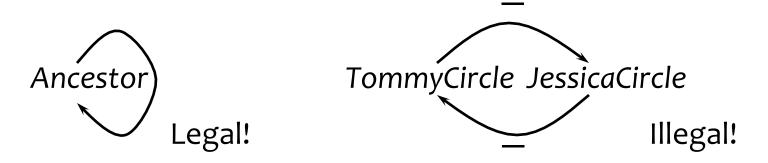

uid	name	age	рор
142	Bart	10	0.9
121	Allison	8	0.85

# Legal mix of negation and recursion

- Construct a dependency graph
  - One node for each table defined in WITH
  - A directed edge  $R \rightarrow S$  if R is defined in terms of S
  - Label the directed edge "—" if the query defining *R* is not monotone with respect to *S*
- Legal SQL3 recursion: no cycle with a "-" edge
  - Called stratified negation
- Bad mix: a cycle with at least one edge labeled "-"

### Stratified negation example

• Find pairs of persons with no common ancestors

```
WITH RECURSIVE Ancestor(anc, desc) AS
     ((SELECT parent, child FROM Parent) UNION
      (SELECT al.anc, a2.desc
       FROM Ancestor al, Ancestor a2
       WHERE al.desc = a2.anc)),
     Person(person) AS
                                               Ancesto
     ((SELECT parent FROM Parent) UNION
      (SELECT child FROM Parent)),
     NoCommonAnc(personl, person2) AS
                                               Person
     ((SELECT pl.person, p2.person
       FROM Person pl, Person p2
       WHERE pl.person <> p2.person)
                                               NoCommonAnc
      EXCEPT
      (SELECT al.desc, a2.desc
       FROM Ancestor al, Ancestor a2
       WHERE al.anc = a2.anc)
SELECT * FROM NoCommonAnc;
```

# Evaluating stratified negation

The stratum of a node *R* is the maximum number of "—" edges on any path from *R* in the dependency graph

Person

**NoCommonAnc** 

- Ancestor: stratum o
- Person: stratum o
- NoCommonAnc: stratum 1
- Evaluation strategy
  - Compute tables lowest-stratum first
  - For each stratum, use fixed-point iteration on all nodes in that stratum
    - Stratum o: Ancestor and Person
    - Stratum 1: NoCommonAnc

<sup>©</sup> Intuitively, there is no negation within each stratum

#### Summary

- SQL3 WITH recursive queries
- Solution to a recursive query (with no negation): unique minimal fixed point
- Computing unique minimal fixed point: fixed-point iteration starting from Ø
- Mixing negation and recursion is tricky
  - Illegal mix: fixed-point iteration may not converge; there may be multiple minimal fixed points
  - Legal mix: stratified negation (compute by fixed-point iteration stratum by stratum)
