CompSci 516 Database Systems

Lecture 14
Intro to Transactions

Instructor: Sudeepa Roy

Announcements

HW2 deadline 10/31 (Wed) 11:55 pm!

- Project midterm report due 11/5 (Mon, extended)
 - Keep working on your proposed project too
 - Send me an email if you want to discuss your project

Where are we now?

We learnt

- ✓ Relational Model and Query Languages
 - ✓ SQL, RA, RC
 - √ Postgres (DBMS)
 - HW1
- ✓ Database Normalization
- ✓ DBMS Internals
 - ✓ Storage
 - ✓ Indexing
 - ✓ Query Evaluation
 - ✓ Operator Algorithms
 - ✓ External sort
 - ✓ Query Optimization
- ✓ Map-reduce and spark
 - HW2

Next

- Transactions
 - Basic concepts
 - Concurrency control
 - Recovery
 - (for the next 4-5 lectures)

Reading Material

• [RG]

- Chapter 16.1-16.3, 16.4.1
- -17.1-17.4
- **–** 17.5.1, 17.5.3

Acknowledgement:

The following slides have been created adapting the instructor material of the [RG] book provided by the authors Dr. Ramakrishnan and Dr. Gehrke.

Motivation: Concurrent Execution

- Concurrent execution of user programs is essential for good DBMS performance.
 - Disk accesses are frequent, and relatively slow
 - it is important to keep the CPU busy by working on several user programs concurrently
 - short transactions may finish early if interleaved with long ones
 - may increase system throughput (avg. #transactions per unit time) and decrease response time (avg. time to complete a transaction)
- A user's program may carry out many operations on the data retrieved from the database
 - but the DBMS is only concerned about what data is read/written from/to the database

Transactions

- A transaction is the DBMS's abstract view of a user program
 - a sequence of reads and write
 - the same program executed multiple times would be considered as different transactions
 - DBMS will enforce some ICs, depending on the ICs declared in CREATE TABLE statements
 - Beyond this, the DBMS does not really understand the semantics of the data. (e.g., it does not understand how the interest on a bank account is computed)

Example

Consider two transactions:

```
T1: BEGIN A=A+100, B=B-100 END
T2: BEGIN A=1.06*A, B=1.06*B END
```

- Intuitively, the first transaction is transferring \$100 from B's account to A's account. The second is crediting both accounts with a 6% interest payment
- There is no guarantee that T1 will execute before T2 or vice-versa, if both are submitted together.
- However, the net effect *must* be equivalent to these two transactions running serially in some order

Example

T1: BEGIN A=A+100, B=B-100 END T2: BEGIN A=1.06*A, B=1.06*B END

Consider a possible interleaving (schedule):

T1: A=A+100, B=B-100

T2: A=1.06*A, B=1.06*B

* This is OK. But what about:

T1: A=A+100, B=B-100

T2: A=1.06*A, B=1.06*B

The DBMS's view of the second schedule:

T1: R(A), W(A), R(B), W(B)

T2: R(A), W(A), R(B), W(B)

Duke CS, Fall 2018

CompSci 516: Database Systems

Commit and Abort

- A transaction might commit after completing all its actions
- or it could abort (or be aborted by the DBMS) after executing some actions

Concurrency Control and Recovery

T1: BEGIN A=A+100, B=B-100 END T2: BEGIN A=1.06*A, B=1.06*B END

Concurrency Control

- (Multiple) users submit (multiple) transactions
- Concurrency is achieved by the DBMS, which interleaves actions (reads/writes of DB objects) of various transactions
- user should think of each transaction as executing by itself one-at-a-time
- The DBMS needs to handle concurrent executions

Recovery

- Due to crashes, there can be partial transactions
- DBMS needs to ensure that they are not visible to other transactions

ACID Properties

- Atomicity
- Consistency
- Isolation
- Durability

Atomicity

- A user can think of a transaction as always executing all its actions in one step, or not executing any actions at all
 - Users do not have to worry about the effect of incomplete transactions

Consistency

- Each transaction, when run by itself with no concurrent execution of other actions, must preserve the consistency of the database
 - e.g. if you transfer money from the savings account to the checking account, the total amount still remains the same

Isolation

- A user should be able to understand a transaction without considering the effect of any other concurrently running transaction
 - even if the DBMS interleaves their actions
 - transaction are "isolated or protected" from other transactions

Durability

T1: BEGIN A=A+100, B=B-100 END T2: BEGIN A=1.06*A, B=1.06*B END

- Once the DBMS informs the user that a transaction has been successfully completed, its effect should persist
 - even if the system crashes before all its changes are reflected on disk

Next, how we maintain all these four properties But, in detail later

Ensuring Consistency

- e.g. Money debit and credit between accounts
- User's responsibility to maintain the integrity constraints
- DBMS may not be able to catch such errors in user program's logic
 - e.g. if the credit is (debit 1)
- However, the DBMS may be in inconsistent state "during a transaction" between actions
 - which is ok, but it should leave the database at a consistent state when it commits or aborts
- Database consistency follows from transaction consistency, isolation, and atomicity

Ensuring Isolation

- DBMS guarantees isolation (later, how)
- If T1 and T2 are executed concurrently, either the effect would be T1->T2 or T2->T1 (and from a consistent state to a consistent state)
- But DBMS provides no guarantee on which of these order is chosen
- Often ensured by "locks" but there are other methods too

Ensuring Atomicity

- Transactions can be incomplete due to several reasons
 - Aborted (terminated) by the DBMS because of some anomalies during execution
 - in that case automatically restarted and executed anew
 - The system may crash (say no power supply)
 - A transaction may decide to abort itself encountering an unexpected situation
 - e.g. read an unexpected data value or unable to access disks

Ensuring Atomicity

- A transaction interrupted in the middle can leave the database in an inconsistent state
- DBMS has to remove the effects of partial transactions from the database
- DBMS ensures atomicity by "undoing" the actions of incomplete transactions
- DBMS maintains a "log" of all changes to do so

Ensuring Durability

- The log also ensures durability
- If the system crashes before the changes made by a completed transactions are written to the disk, the log is used to remember and restore these changes when the system restarts
- "recovery manager" will be discussed later
 - takes care of atomicity and durability

Notations

```
T1: BEGIN A=A+100, B=B-100 END
T2: BEGIN A=1.06*A, B=1.06*B END
```

- Transaction is a list of "actions" to the DBMS
 - includes "reads" and "writes"
 - $-R_{T}(O)$: Reading an object O by transaction T
 - W_T(O): Writing an object O by transaction T
 - also should specify $Commit_T (C_T)$ and $Abort_T (A_T)$
 - T is omitted if the transaction is clear from the context

Assumptions

- Transactions communicate only through READ and WRITE
 - i.e. no exchange of message among them

- A database is a fixed collection of independent objects
 - i.e. objects are not added to or deleted from the database
 - this assumption can be relaxed
 - (dynamic db/phantom problem later)

Schedule

- An actual or potential sequence for executing actions as seen by the DBMS
- A list of actions from a set of transactions
 - includes READ, WRITE, ABORT, COMMIT
- Two actions from the same transaction T MUST appear in the schedule in the same order that they appear in T
 - cannot reorder actions from a given transaction

Serial Schedule

| T1 | T2 | | |
|-----------|--------|--|--|
| R(A) | | | |
| W(A) | | | |
| R(B) | | | |
| W(B) | | | |
| COMMIT | | | |
| | R(A) | | |
| | W(A) | | |
| | R(B) | | |
| | W(B) | | |
| | COMMIT | | |

- If the actions of different transactions are not interleaved
 - transactions are executed from start to finish one by one

Problems with a serial schedule

- The same motivation for concurrent executions, e.g.
 - while one transaction is waiting for page I/O from disk, another transaction could use the CPU
 - reduces the time disks and processors are idle
- Decreases system throughput
 - average #transactions computed in a given time
- Also affects response time
 - average time taken to complete a transaction
 - if we relax it, short transactions can be completed with long ones and do not have to wait for them to finish

Scheduling Transactions

- Serial schedule: Schedule that does not interleave the actions of different transactions
- Equivalent schedules: For any database state, the effect (on the set of objects in the database) of executing the first schedule is identical to the effect of executing the second schedule
- Serializable schedule: A schedule that is equivalent to some serial execution of the committed transactions
 - Note: If each transaction preserves consistency, every serializable schedule preserves consistency

Serializable Schedule

- If the effect on any consistent database instance is guaranteed to be identical to that of "some" complete serial schedule for a set of "committed transactions"
- However, no guarantee on T1-> T2 or T2 -> T1

| T1 | T2 | T1 | T2 | T1 | T2 |
|--------|--------|--------|--------|--------|--------|
| R(A) | | R(A) | | | R(A) |
| W(A) | | W(A) | | | W(A) |
| R(B) | | | R(A) | R(A) | |
| W(B) | | | W(A) | | R(B) |
| COMMIT | | R(B) | | | W(B) |
| | R(A) | W(B) | | W(A) | |
| | W(A) | | R(B) | R(B) | |
| | R(B) | | W(B) | W(B) | |
| | W(B) | | COMMIT | | COMMIT |
| | COMMIT | COMMIT | | COMMIT | |

serial schedule

serializable schedules

Anomalies with Interleaved Execution

 If two consistency-preserving transactions when run interleaved on a consistent database might leave it in inconsistent state

- Write-Read (WR)
- Read-Write (RW)
- Write-Write (WW)

No conflict with RR if no write is involved

WR Conflict

T1: R(A), W(A), R(B), W(B), Abort
T2: R(A), W(A), Commit

T1: R(A), W(A), R(B), W(B), Commit T2: R(A), W(A), R(B), W(B), Commit T2: R(A), W(A), R(B), W(B), Commit R(B), W(B), W(B), Commit R(B), W(B), W(B),

- Reading Uncommitted Data (WR Conflicts, "dirty reads"):
 - transaction T2 reads an object that has been modified by T1 but not yet committed
 - or T2 reads an object from an inconsistent database state (like fund is being transferred between two accounts by T1 while T2 adds interests to both)

RW Conflict

T1: R(A), R(A), W(A), C

T2: R(A), W(A), C

Unrepeatable Reads (RW Conflicts):

- T2 changes the value of an object A that has been read by transaction T1, which is still in progress
- If T1 tries to read A again, it will get a different result
- Suppose two customers are trying to buy the last copy of a book simultaneously

WW conflict

```
T1: W(A), W(B), C
T2: W(A), W(B), C
```

- Overwriting Uncommitted Data (WW Conflicts, "lost update"):
 - T2 overwrites the value of A, which has been modified by T1, still in progress
 - Suppose we need the salaries of two employees (A and B) to be the same
 - T1 sets them to \$1000
 - T2 sets them to \$2000

Schedules with Aborts

T1: R(A), W(A), Abort

T2: R(A), W(A) Commit

- Actions of aborted transactions have to be undone completely
 - may be impossible in some situations
 - say T2 reads the fund from an account and adds interest
 - T1 aims to deposit money but aborts
 - if T2 has not committed, we can "cascade aborts" by aborting T2 as well
 - if T2 has committed, we have an "unrecoverable schedule"

Recoverable Schedule

Example of Unrecoverable schedule

T1: R(A), W(A), Abort

T2: R(A), W(A), R(B), W(B), Commit

- Transaction commits if and only after all transactions they read have committed
 - avoids cascading aborts

Conflict Equivalent Schedules

- Two schedules are conflict equivalent if:
 - Involve the same actions of the same transactions
 - Every pair of conflicting actions of two committed transactions is ordered the same way
- Conflicting actions:
 - both by the same transaction T_i
 - R_i(X), W_i(Y)
 - both on the same object by two transactions T_i and T_j, at least one action is a write
 - R_i(X), W_i(X)
 - $W_i(X)$, $R_i(X)$
 - W_i(X), W_i(X)

Conflict Equivalent Schedules

- Two conflict equivalent schedules have the same effect on a database
 - all pairs of conflicting actions are in same order
 - one schedule can be obtained from the other by swapping "non-conflicting" actions
 - either on two different objects
 - or both are read on the same object

Conflict Serializable Schedules

 Schedule S is conflict serializable if S is conflict equivalent to some serial schedule

- In class:
- $r_1(A)$; $w_1(A)$; $r_2(A)$; $w_2(A)$; $r_1(B)$; $w_1(B)$; $r_2(B)$; $w_2(B)$
- to
- $r_1(A)$; $w_1(A)$; $r_1(B)$; $w_1(B)$; $r_2(A)$; $w_2(A)$; $r_2(B)$; $w_2(B)$

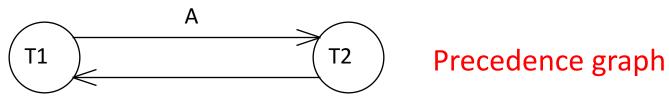

Example

A schedule that is not conflict serializable:

T1: R(A), W(A), R(B), W(B)
T2: R(A), W(A), R(B), W(B)

can write it in this equivalent way as well

$$R_1(A), W_1(A), R_2(A), W_2(A), R_2(B), W_2(B), R_1(B), W_1(B)$$

The cycle in the graph reveals the problem.
 The output of T1 depends on T2, and viceversa.

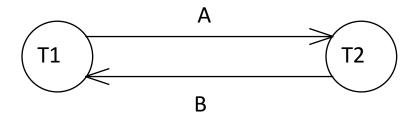

Precedence Graph

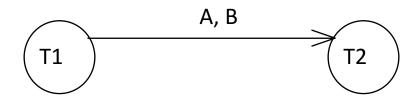

- Also called dependency graph, conflict graph, or serializability graph
- One node per committed transaction
- Edge from T_i to T_j if an action of T_i precedes and conflicts with one of T_i's actions
 - $-W_i(A) ---R_j(A)$, or
 - $-R_i(A) ---W_i(A)$, or
 - $W_i(A) --- W_i(A)$
- T_i must precede T_i in any serial schedule

Conflict Serializability

 Theorem: Schedule is conflict serializable if and only if its precedence graph is acyclic

 $R_1(A), W_1(A), R_2(A), W_2(A), R_2(B), W_2(B), R_1(B), W_1(B)$

 $r_1(A)$; $w_1(A)$; $r_2(A)$; $w_2(A)$; $r_1(B)$; $w_1(B)$; $r_2(B)$; $w_2(B)$

CompSci 516: Database Systems

Lock-Based Concurrency Control

- DBMS should ensure that only serializable and recoverable schedules are allowed
 - No actions of committed transactions are lost while undoing aborted transactions
- Uses a locking protocol
- Lock: a bookkeeping object associated with each "object"
 - different granularity
- Locking protocol:
 - a set of rules to be followed by each transaction

Strict two-phase locking (Strict 2PL)

Two rules

- Each transaction must obtain
 - a S (shared) lock on object before reading
 - and an X (exclusive) lock on object before writing
 - exclusive locks also allow reading an object, additional shared lock is not required
 - If a transaction holds an X lock on an object, no other transaction can get a lock (S or X) on that object
 - transaction is suspended until it acquires the required lock
- All locks held by a transaction are released when the transaction completes

Example: Strict 2PL

T1: R(A), W(A), R(B), W(B), Commit

T2: R(A), W(A), R(B), W(B), Commit

- WR conflict (dirty read)
- Strict 2PL does not allow this

T1: X(A), R(A), W(A),

T2: HAS TO WAIT FOR LOCK ON A

T1: X(A), R(A), W(A), X(B), R(B), W(B), C

T2: X(A), R(A), W(A), X(B), R(B), W(B), C

All locks released here

Can use UX(A), UX(B) – for shared lock unlocking,

US(A), US(B)

Duke CS, Fall 2018

CompSci 516: Database Systems

Example: Strict 2PL

T1: S(A), R(A), X(C), R(C), W(C), C

T2: S(A), R(A), X(B), R(B), W(B), C

Strict 2PL allows interleaving

More on Strict 2PL

Every transaction has

- a growing phase of acquiring locks, and
- a shrinking phase of releasing locks

Strict 2PL allows only serializable schedules

- precedence graphs will be acyclic (check yourself)
- Additionally, allows recoverable schedules and simplifies transaction aborts
- two transactions can acquire locks on different objects independently

2PL vs. strict 2PL

- 2PL:
 - first, acquire all locks, release none
 - second, release locks, cannot acquire any other lock
- Strict 2PL:
 - release write (X) lock, only after it has ended (committed or aborted)
- (Non-strict) 2PL also allows only serializable schedules like strict 2PL, but involves more complex abort processing

Strict 2PL and Conflict Serializability

- Strict 2PL allows only schedules whose precedence graph is acyclic
- Can never allow cycles as the X locks are being held by one transaction
- However, it is sufficient but not necessary for serializability
- Relaxed solution: View serializability

View Serializability

- Schedules S1 and S2 are view equivalent if:
 - If T_i reads initial value of A in S₁, then T_i also reads initial value of A in S₂
 - If T_i reads value of A written by T_j in S₁, then T_i also reads value of A written by T_i in S₂,
 - For all data object A, if T_i writes final value of A in S₁, then T_i also writes final value of A in S₂
- S is view serializable, if it is view equivalent to some serial schedule

S1 (view serializable, not conflict serializable)

S2 (serial)

```
T1: R(A) W(A) C
T2: W(A) C
T3: W(A) C
```

```
T1: R(A),W(A) C
T2: W(A) C
T3: W(A) C
```

More on View Serializability

- Every conflict serializable schedule is view serializable (check it yourself)
- But the converse may not be true
- If VS but not CS, would contain a "blind write" (see below)
- Verifying and enforcing VS is more expensive than CS, so less popular than CS

S1 (view serializable, not conflict serializable)

S2 (serial)

T1: R(A) W(A) C T2: W(A) C T3: W(A) C T1: R(A),W(A) C T2: W(A) C T3: W(A) C

Lock Management

- Lock and unlock requests are handled by the lock manager
- Lock table entry:
 - Number of transactions currently holding a lock
 - Type of lock held (shared or exclusive)
 - Pointer to queue of lock requests (if the shared or exclusive lock cannot be granted immediately)
- Locking and unlocking have to be atomic operations
- Lock upgrade: transaction that holds a shared lock can be upgraded to hold an exclusive lock
- Transaction commits or aborts
 - all locks released

Deadlocks

- Deadlock: Cycle of transactions waiting for locks to be released by each other
 - database systems periodically check for deadlocks

- Two ways of dealing with deadlocks:
 - Deadlock detection
 - Deadlock prevention

Deadlock Detection

- 1. Create a waits-for graph: (example on next slide)
 - Nodes are transactions
 - There is an edge from T_i to T_j if T_i is waiting for T_j to release a lock
- Periodically check for cycles in the waits-for graph
- Abort a transaction on a cycle and release its locks, proceed with the other transactions
 - several choices
 - one with the fewest locks
 - one has done the least work/farthest from completion
 - if being repeatedly restarted, should be favored at some point
- Use timeout, if long delay, assume (pessimistically) a deadlock

Deadlock Detection

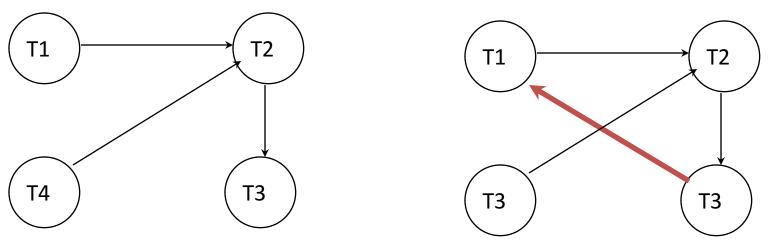

Example:

T1: S(A), R(A), S(B)

T2: X(B),W(B) X(C)

T3: S(C), R(C) X(A)

T4: X(B)

Duke CS, Fall 2018

CompSci 516: Database Systems

Deadlock Prevention

- Assign priorities based on timestamps
- Assume T_i wants a lock that T_i holds. Two policies are possible:
 - Wait-Die: It T_i has higher priority, T_i waits for T_i; otherwise T_i aborts
 - Wound-wait: If T_i has higher priority, T_i aborts; otherwise T_i waits
- Convince yourself that no cycle is possible
- If a transaction re-starts, make sure it has its original timestamp
 - each transaction will be the oldest one and have the highest priority at some point
- A variant of strict 2PL, conservative 2PL, works too
 - acquire all locks it ever needs before a transaction starts
 - no deadlock but high overhead and poor performance, so not used in practice

Summary

- Transaction
 - $R_1(A), W_2(A),$
 - Commit C₁, abort A₁
 - Lock/unlock: $S_1(A)$, $X_1(A)$, $US_1(A)$, $UX_1(A)$
- ACID properties
 - what they mean, whose responsibility to maintain each of them
- Conflicts: RW, WR, WW
- 2PL/Strict 2PL
 - all lock acquires have to precede all lock releases
 - Strict 2PL: release X locks only after commit or abort

Summary

Schedule

- Serial schedule
- Serializable schedule (why do we need them?)
- Conflicting actions
- Conflict-equivalent schedules
- Conflict-serializable schedule
- View-serializable schedule (relaxation)
- Conflict Serializability => View Serializability => Serializability
- Recoverable schedules
- Dependency (or Precedence) graphs
 - their relation to conflict serializability (by acyclicity)
 - their relation to Strict 2PL

Summary

- Lock management basics
- Deadlocks
 - detection
 - waits-for graph has cycle, or timeout
 - what to do if deadlock is detected
 - prevention
 - wait-die and wound-wait
