

Why Study Games?

- Many human activities can be modeled as games
 - Negotiations
 - Bidding
 - TCP/IP
 - Military confrontations
 - Pursuit/Evasion
- Games are used to train the mind
- Human game-playing, animal play-fighting

Why Are Games Good for AI?

- · Games typically have concise rules
- Well-defined starting and end points
- Sensing and effecting are simplified

 Not true for sports games
 See robocup
- · Games are fun!
- Downside: Getting taken seriously (not) – See robo search and rescue

History of Games in AI

- Computer games have been around almost as long as computers (perhaps longer)
 - Chess: Turing (and others) in the 1950s
 - Checkers: Samuel, 1950s learning program
- Usually start with naïve optimism
- · Follow with naïve pessimism
- Simon: Computer chess champ by 1967
- Many, e.g., Kasparov, predicted that a computer would *never* be champion

Games Today

- Computers perform at champion level

 Backgammon, Checkers, Chess, Othello
- Computers perform well
 Bridge
- · Computers still do badly

– Go, Hex

Game Setup

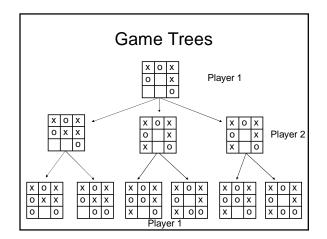

- Most commonly, we study games that are:
 - 2 player
 - AlternatingZero-sum
 - Perfect information
- Examples: Checkers, chess, backgammon
- Assumptions can be relaxed at some expense
- Economics studies case where number of agents is very large
 - Individual actions don't change the dynamics

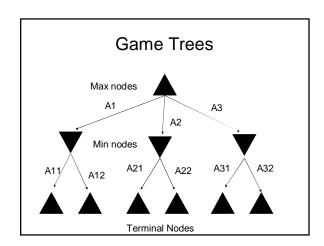

Zero Sum Games

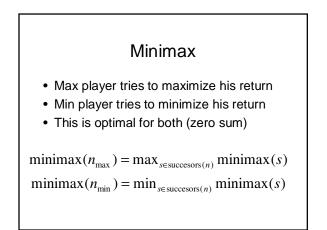

- Assign values to different outcomes
- Win = 1, Loss = -1
- With zero sum games every gain comes at the other player's expense
- Sum of both player's scores must be 0
- Are any games truly zero sum?

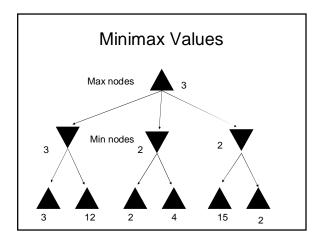

Characterizing Games

- Two-player games very much like search
 - Initial state
 - Successor function
 - Terminal test
 - Objective function (heuristic function)
- Unlike search
 - Terminal states are often a large set
 - Full search to terminal states usually impossible

Minimax Properties

- Minimax can be run depth first

 Time O(b^m)
 Space O(bm)
- · Assumes that opponent plays optimally
- Based on a worst-case analysis
- What if this is incorrect?

Minimax in the Real World

- Search trees are too big
- Alternating turns double depth of the search
 2 ply = 1 full turn
- Branching factors are too high
 - Chess: 35
 - Go: 361
- Search from start never terminates in nontrivial games

Evaluation Functions

- · Like heuristic functions
- Try to estimate value of a node without expanding all the way to termination
- Using evaluation functions
 - Do a depth-limited search
 - Treat evaluation function as if it were terminal
- What's wrong with this?

Desiderata for Evaluation Functions

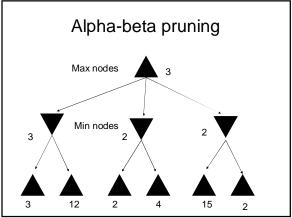

- Would like to put the same ordering on nodes (even if values aren't totally right)
- Is this a reasonable thing to ask for?
- What if you have a perfect evaluation function?
- How are evaluation functions made in practice?
 - Buckets
 - Linear combinations
 - Chess pieces (material)
 - Board control (positional, strategic)

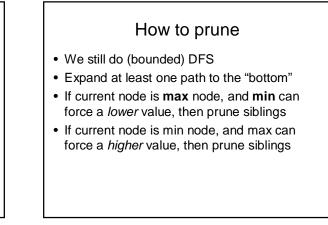

Search Control Issues

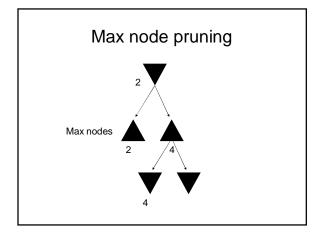

- · Horizon effects
 - Sometimes something interesting is just beyond the horizon
 - How do you know?
- When to generate more nodes?
- If you selectively extend your frontier, how do you decide where?
- If you have a fixed amount of total game time, how do you allocate this?

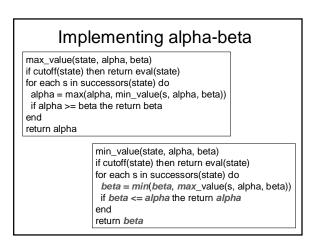

Pruning

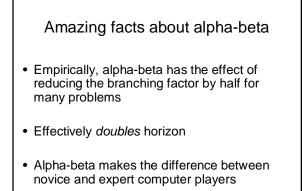

- The most important search control method is figuring out which nodes you don't need to expand
- Use the fact that we are doing a worst-case analysis to our advantage
 - Max player cuts off search when he knows min player can force a provably bad outcome
 - Min player cuts of search when he knows max can force a provably good (for max) outcome

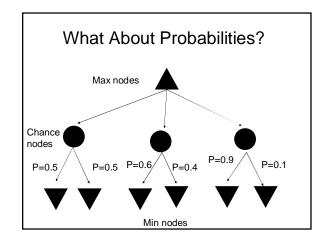

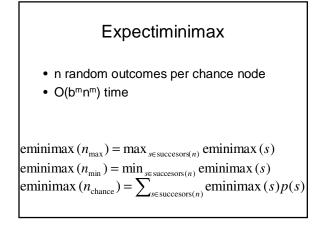

Expectiminimax is nasty

- · High branching factor
- · Randomness makes evaluation fns difficult
 - Hard to predict many steps into future
 - Values tend to smear together
 - Preserving order is not sufficient
- Pruning chances nodes is problematic
 - Prune based upon bound on an expectationNeed a priori bounds on the evaluation function

Multiplayer Games

- Things sort-of generalize
- We can maintain a vector of possible values for each player at each node
- · Assume that each player acts greedily
- What's wrong with this?

Conclusions

- Game tree search is a special kind of search
- Rely heavily on heuristic evaluation functions
- Alpha-beta is a big win
- · Most successful players use alpha-beta
- Final thoughts:
 - Search effort vs. evaluation function effort
 - When to invest in your evaluation function?
