CompSci 516
Database Systems

Lecture 24
Parallel DBMS

Instructor: Sudeepa Roy

Review (Selinger Query Opt)

Where are we now?

Relational model, queries, db design
- Relational Model
- Normal Forms, FD
- Query in SQL / RA / RC
- Recursion

Beyond Relational Model
- XML
- NOSQL **JSON/MongoDB**

Transactions
- Basics
- Concurrency Control
- Recovery

DBMS Internals and Query Processing
- Storage
- Index
- Join algo/Sorting
- Execution/ Optimization

(Basic) Big Data Processing
- Map-Reduce/ Spark
- Parallel DBMS
- Distributed DBMS

Other Topics
- Data Mining
- Data Cube

Covered

Next

To be covered

Announcements (Tues, 4/5)

- HW3 due today noon
- Focus on Project from now on - no more graded quiz!
  - Due 4/13 next Wed + extra time until Friday noon
  - For everything -- report, code, video
  - Do not focus on GUI – anything basic and functional is fine
- 5 mins presentation video – instructions to be posted on Ed
- Course evaluations open – your feedback is very important for improving the class
  - Small token of appreciation 75% - 2 extra points and 90% - 4 extra points to your final exam score for everyone in class

Reading Material

- [RG]
  - Parallel DBMS: Chapter 22.1-22.5
  - Distributed DBMS: Chapter 22.6 – 22.14
- [GUW]
  - Parallel DBMS and map-reduce: Chapter 20.1-20.2
  - Distributed DBMS: Chapter 20.3, 20.4.1-20.4.2, 20.5-20.6
- Other recommended readings:
  - Chapter 2 (Sections 1,2,3) of Mining of Massive Datasets, by Rajaraman and Ullman: http://i.stanford.edu/~ullman/mmds.html
  - Original Google MR paper by Jeff Dean and Sanjay Ghemawat, OSDI' 04: http://research.google.com/archive/mapreduce.html

Acknowledgement:
The following slides have been created adapting the instructor material of the [RG] book provided by the authors Dr. Ramakrishnan and Dr. Gehrke.

Parallel DBMS

Parallel vs. Distributed DBMS

Parallel DBMS

- Parallelization of various operations
  - e.g., loading data, building indexes, evaluating queries
- Data may or may not be distributed initially
- Distribution is governed by performance consideration

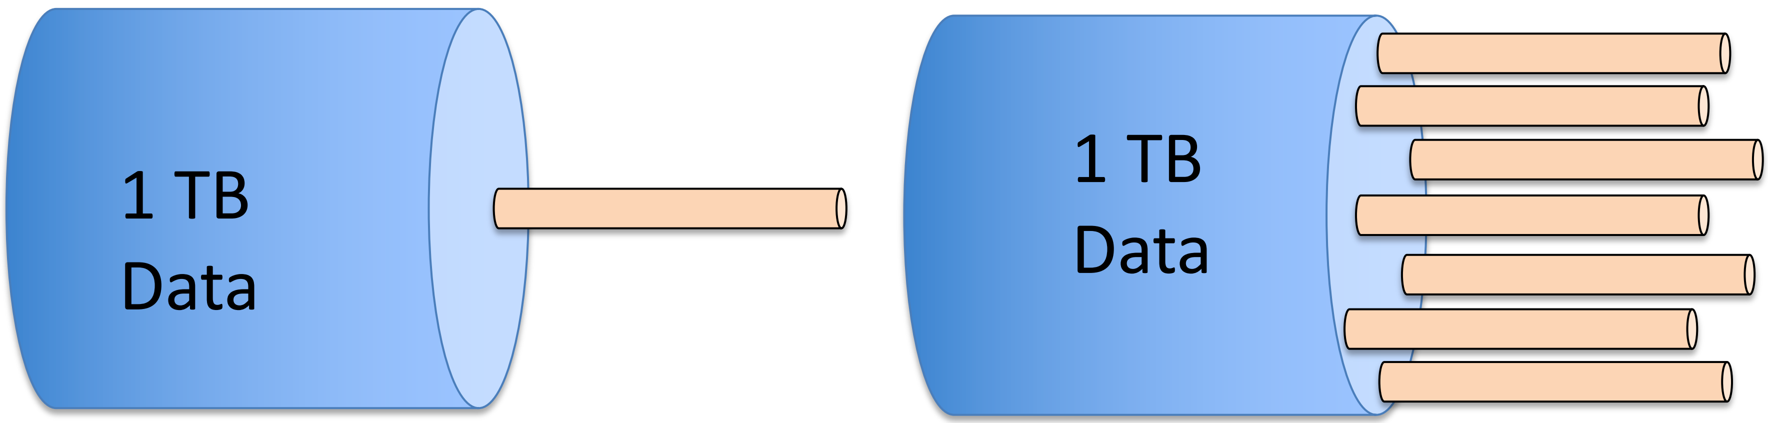
Distributed DBMS

- Data is physically stored across different sites
  - Each site is typically managed by an independent DBMS
- Location of data and autonomy of sites have an impact on Query opt., Conc. Control and recovery
- Also governed by other factors:
  - increased availability for system crash
  - local ownership and access

Why Parallel Access To Data?

At 10 MB/s
1.2 days to scan

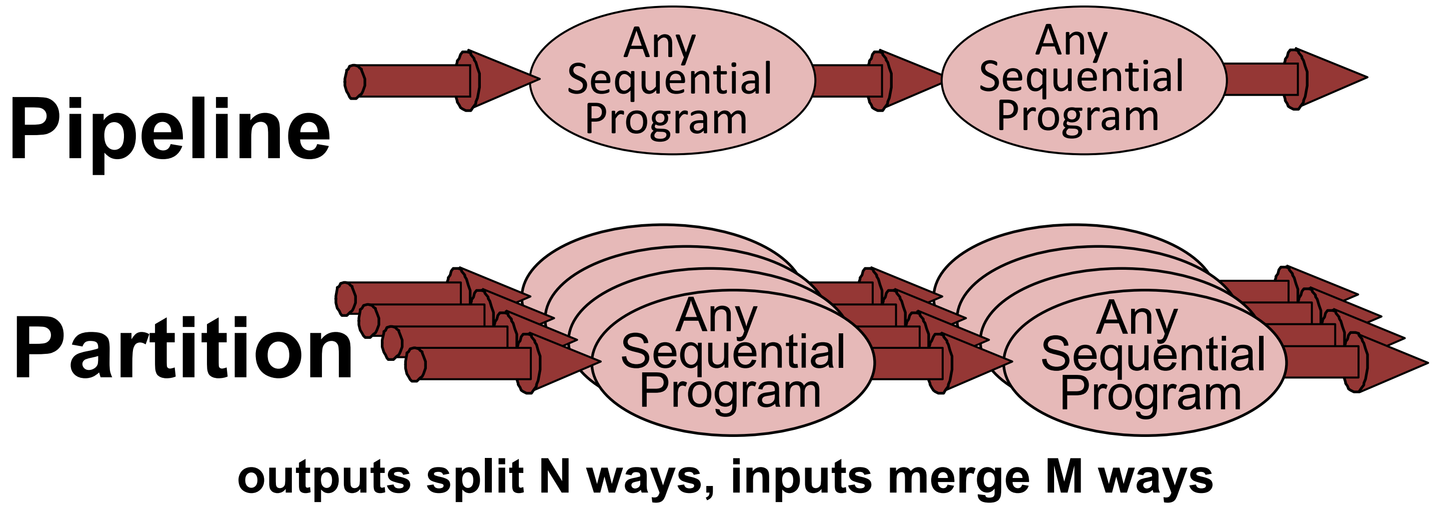
1,000 x parallel
1.5 minute to scan.



Parallelism:
divide a big problem
into many smaller ones
to be solved in parallel.

Parallel DBMS

- Parallelism is natural to DBMS processing
  - Pipeline parallelism: many machines each doing one step in a multi-step process.
  - Data-partitioned parallelism: many machines doing the same thing to different pieces of data.
  - Both are natural in DBMS!



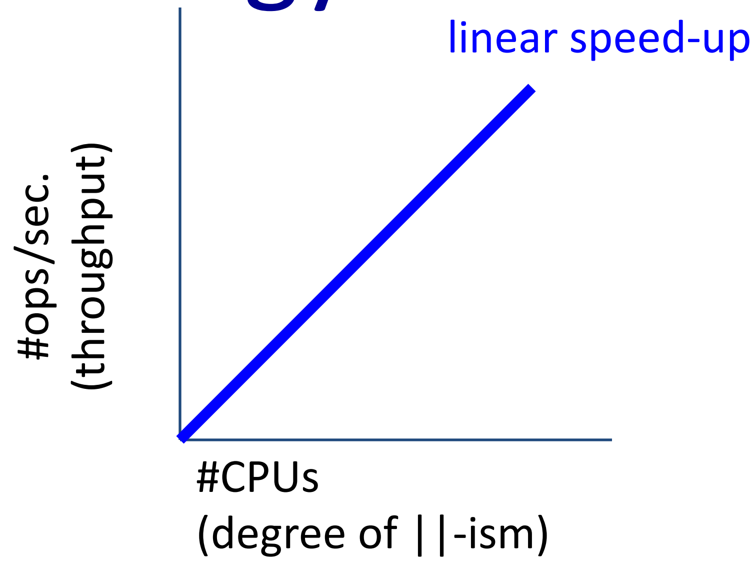
DBMS: The parallel Success Story

- DBMSs are the most successful application of parallelism
  - Teradata (1979), Tandem (1974, later acquired by HP),..
  - Every major DBMS vendor has some parallel server
- Reasons for success:
  - Bulk-processing (= partition parallelism)
  - Natural pipelining
  - Inexpensive hardware can do the trick
  - Users/app-programmers don’t need to think in parallel

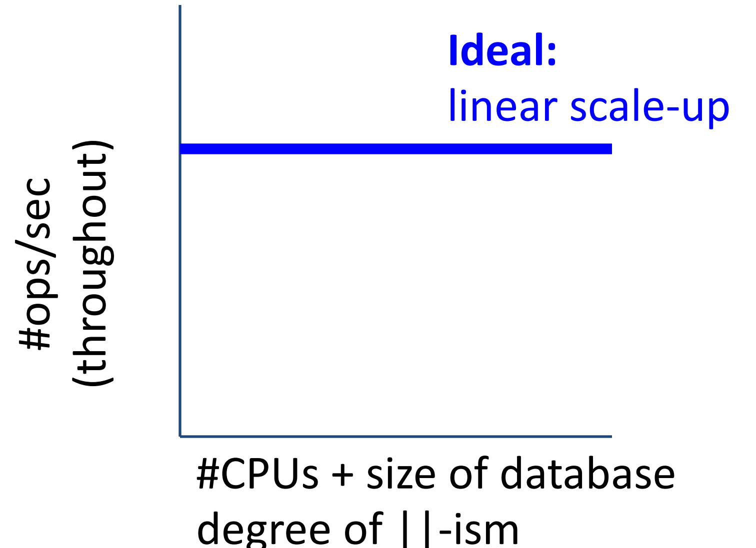
Some || Terminology

Ideal graphs

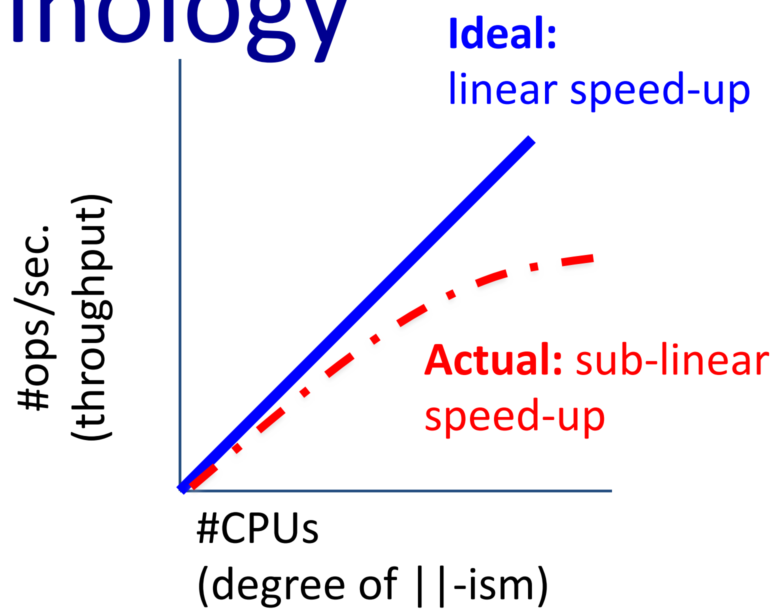
- Speed-Up
  - More resources means proportionally less time for given amount of data.



- Scale-Up
  - If resources increased in proportion to increase in data size, time is constant.



Some || Terminology



In practice

- Due to overhead in parallel processing
- Start-up cost

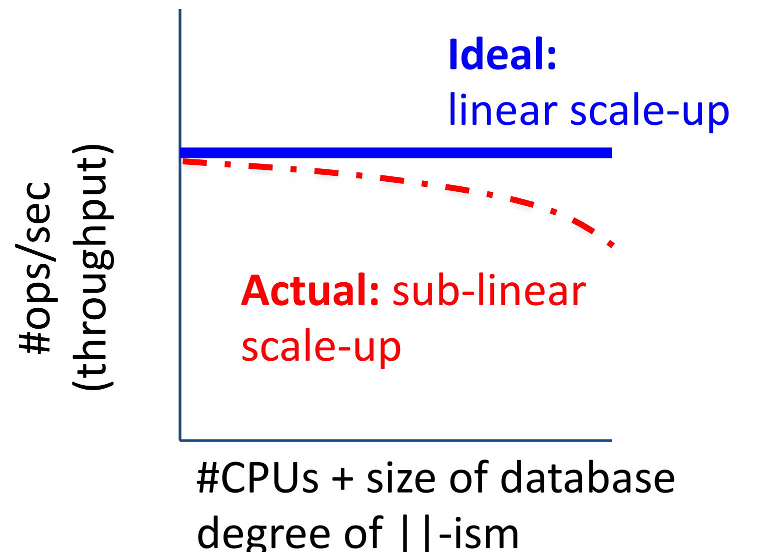
Starting the operation on many processor, might need to distribute data

- Interference

Different processors may compete for the same resources

- Skew

The slowest processor (e.g. with a huge fraction of data) may become the bottleneck



Basics of Parallelism

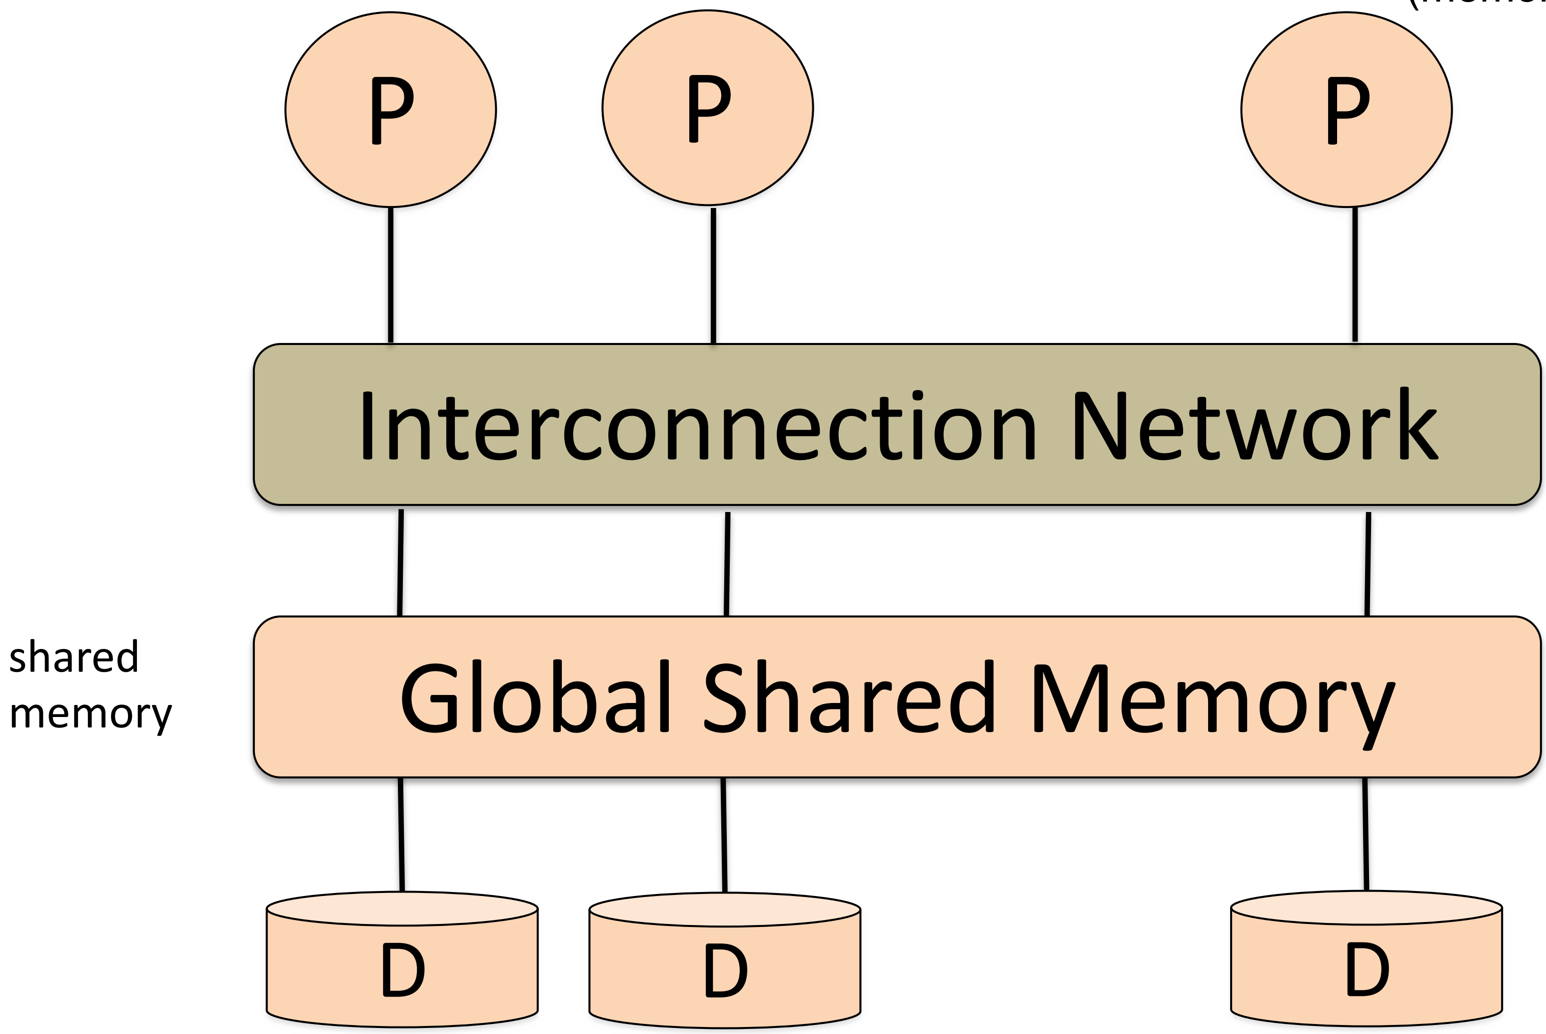
- Units: a collection of processors
  - assume always have local cache
  - may or may not have local memory or disk (next)

- A communication facility to pass information among processors
  - a shared bus or a switch

- Different architecture
  - Whether memory AND/OR disk are shared

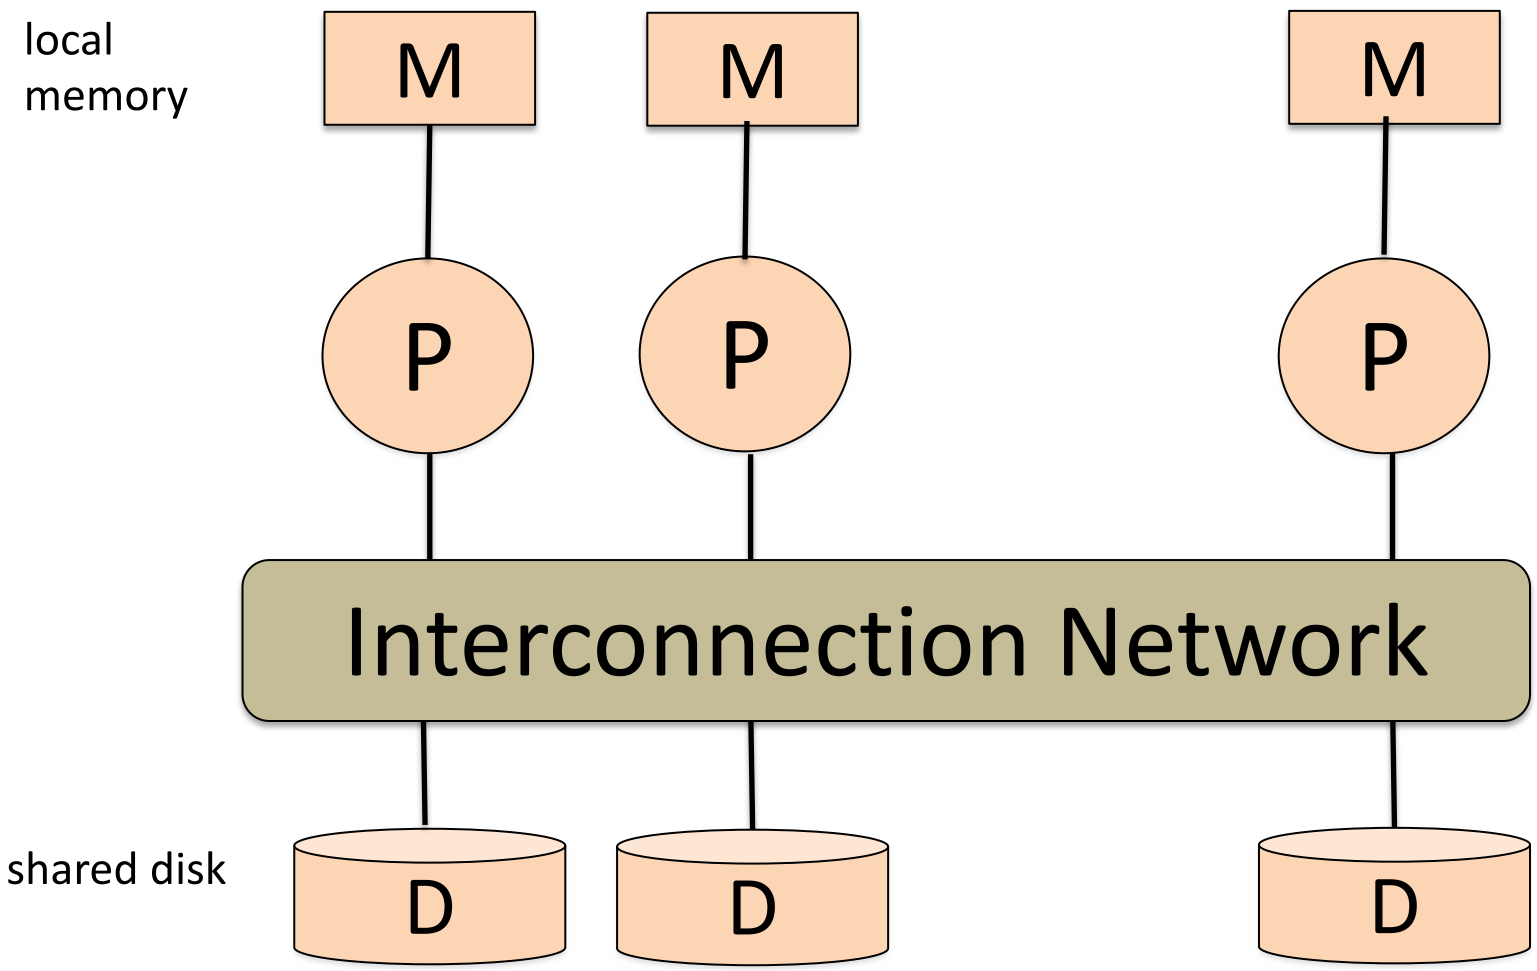
Shared Memory

- Easy to program
- Expensive to build
- Low communication overhead: shared mem.
- Difficult to scaleup (memory contention)



Shared Disk

- Trade-off but still interference like shared-memory (contention of memory and nw bandwidth)



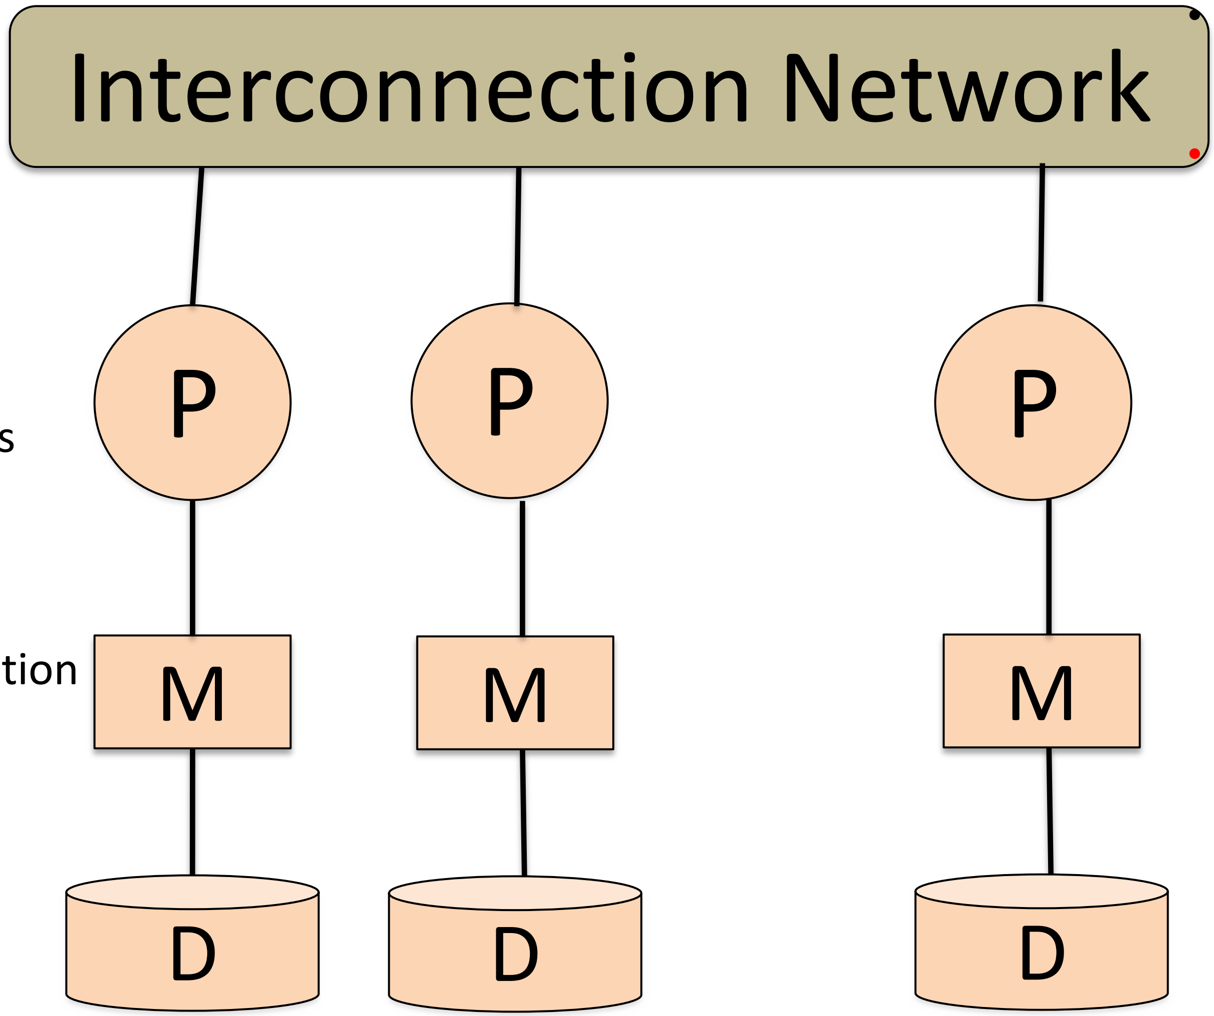
Shared Nothing

- Hard to program and design parallel algos
- Cheap to build
- Easy to scaleup and speedup
- Considered to be the best architecture
- We will assume this architecture!

local memory and disk

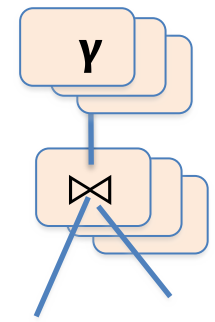
no two CPU can access the same storage area

all communication through a network connection

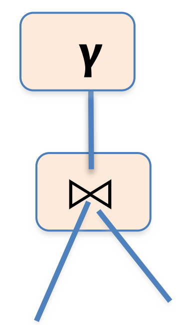


Different Types of DBMS Parallelism

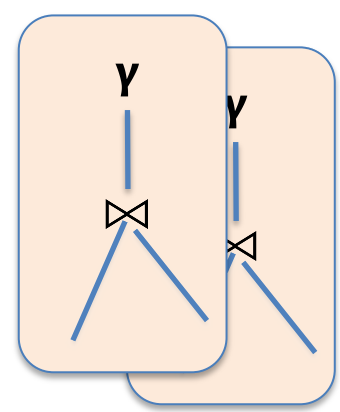
- Intra-operator parallelism
  - get all machines working to compute a given operation (scan, sort, join)
  - OLAP (decision support)



- Inter-operator parallelism
  - each operator may run concurrently on a different site (exploits pipelining)
  - For both OLAP and OLTP



- Inter-query parallelism
  - different queries run on different sites
  - For OLTP



- We'll focus on intra-operator parallelism

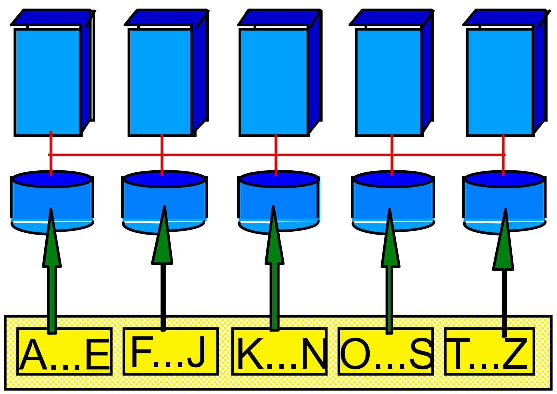
Slide by Prof. Dan Suciu

Data Partitioning

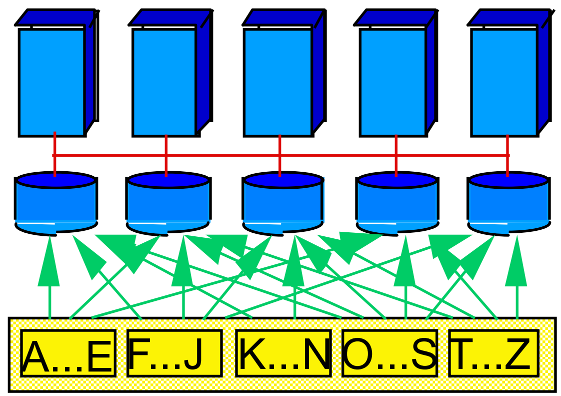
Horizontally Partitioning a table (why horizontal?):

Range-partition



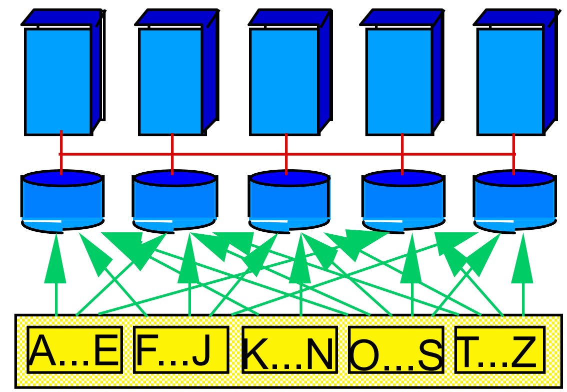
- Good for equijoins, range queries, group-by
- Can lead to data skew

Hash-partition



- Good for equijoins
- But only if hashed on that attribute
- Can lead to data skew

Block-partition or Round Robin

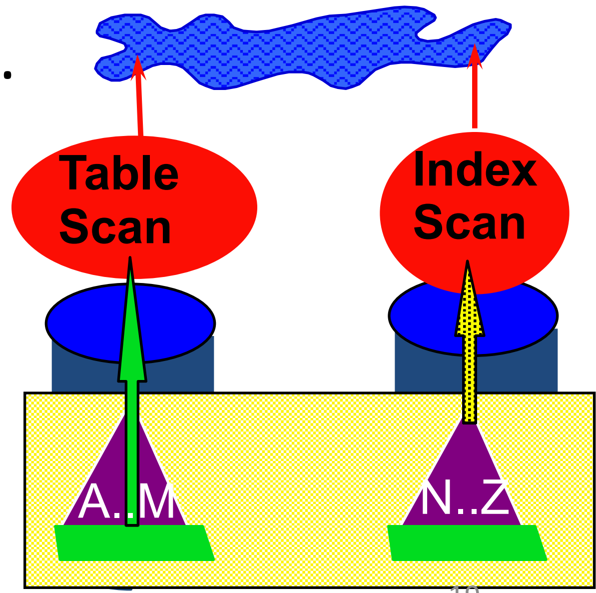


- Send i-th tuple to i-mod-n processor
- Good to spread load
- Good when the entire relation is accessed

Shared disk and memory less sensitive to partitioning,
Shared nothing benefits from "good" partitioning

Best serial plan may not be best ||

- Why?
- Trivial counter-example:
  - Table partitioned with local secondary index at two nodes
  - Range query: all of node 1 and 1% of node 2.
  - Node 1 should do a scan of its partition.
  - Node 2 should use secondary index.



Example problem: Parallel DBMS

R(a,b) is horizontally partitioned across N = 3 machines.

Each machine locally stores approximately 1/N of the tuples in R.

The tuples are randomly organized across machines (i.e., R is block partitioned across machines).

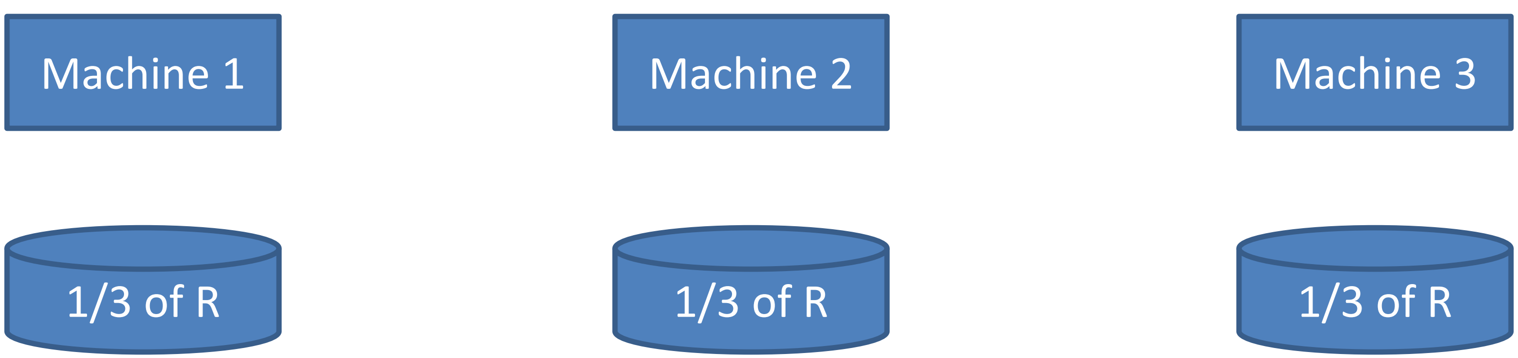
Show a RA plan for this query and how it will be executed across the N = 3 machines.

Pick an efficient plan that leverages the parallelism as much as possible.

- **SELECT a, max(b) as topb**
- **FROM R**
- **WHERE a > 0**
- **GROUP BY a**

R(a, b)

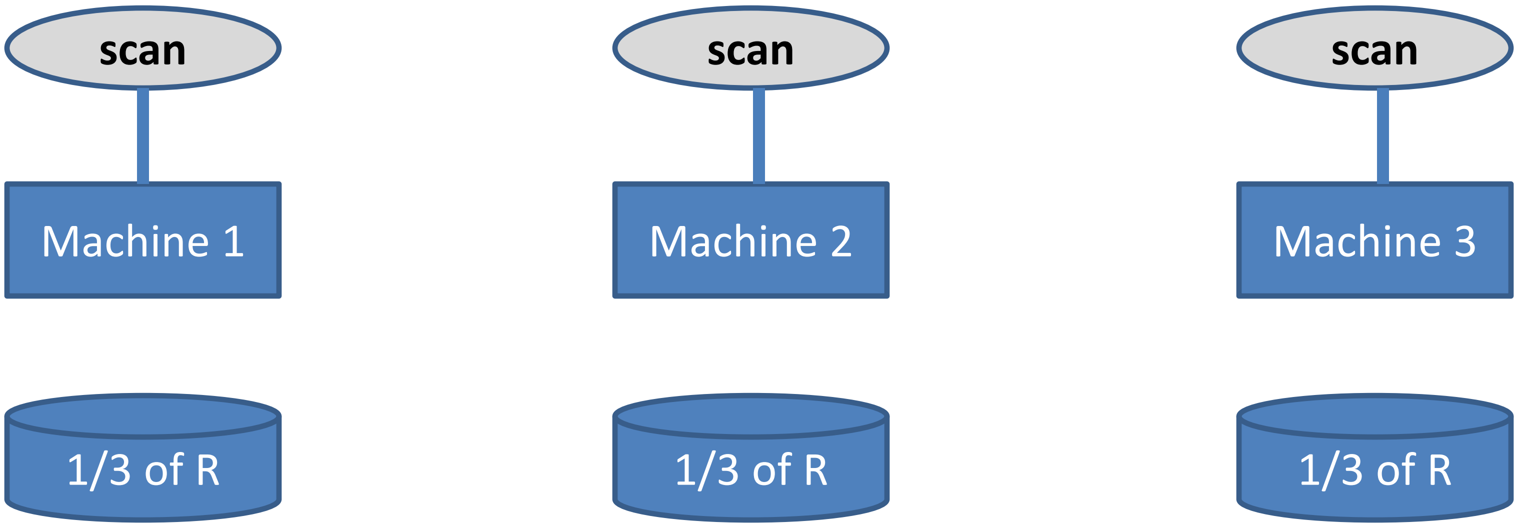
```sql
SELECT a, max(b) as topb
FROM R
WHERE a > 0
GROUP BY a
```



R(a, b)

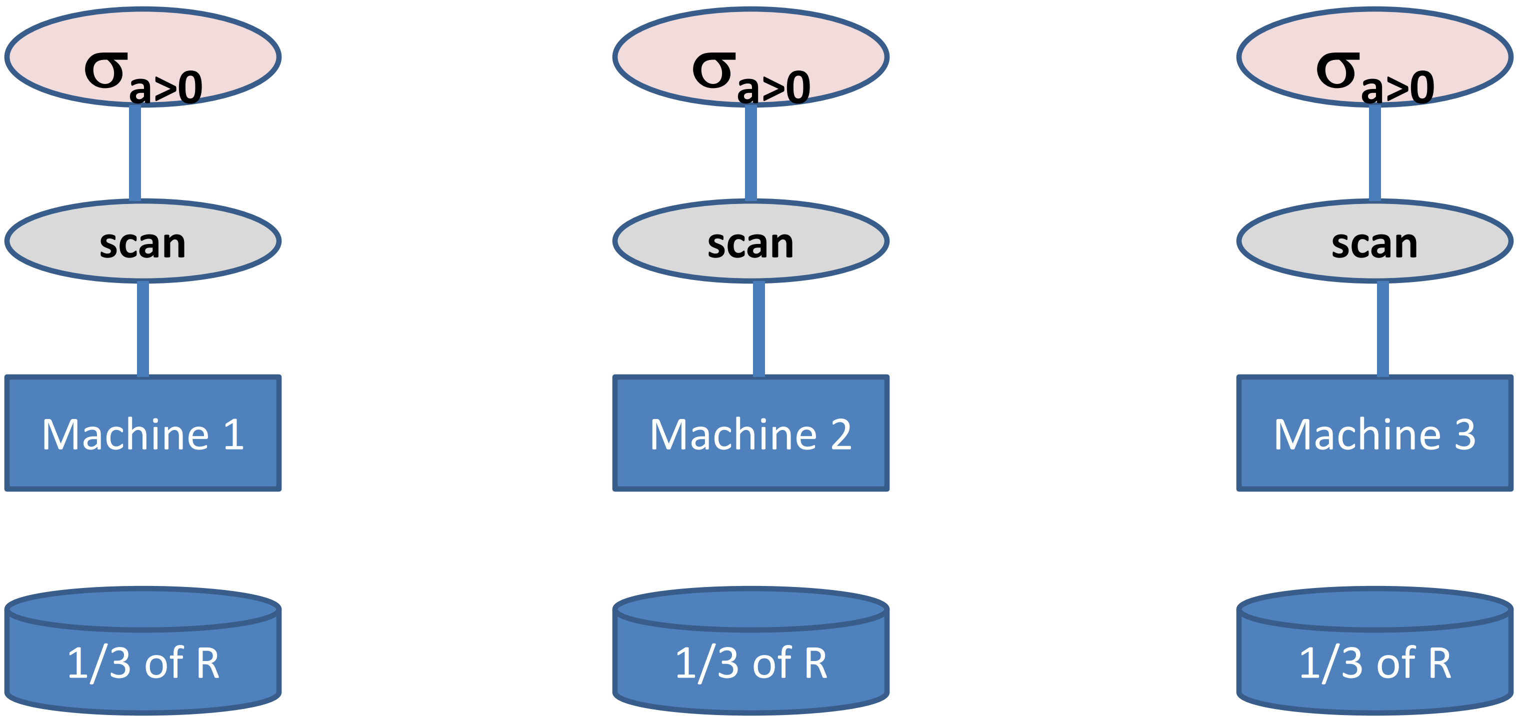
```
SELECT a, max(b) as topb
FROM R
WHERE a > 0
GROUP BY a
```

If more than one relation on a machine, then “scan S”, “scan R” etc



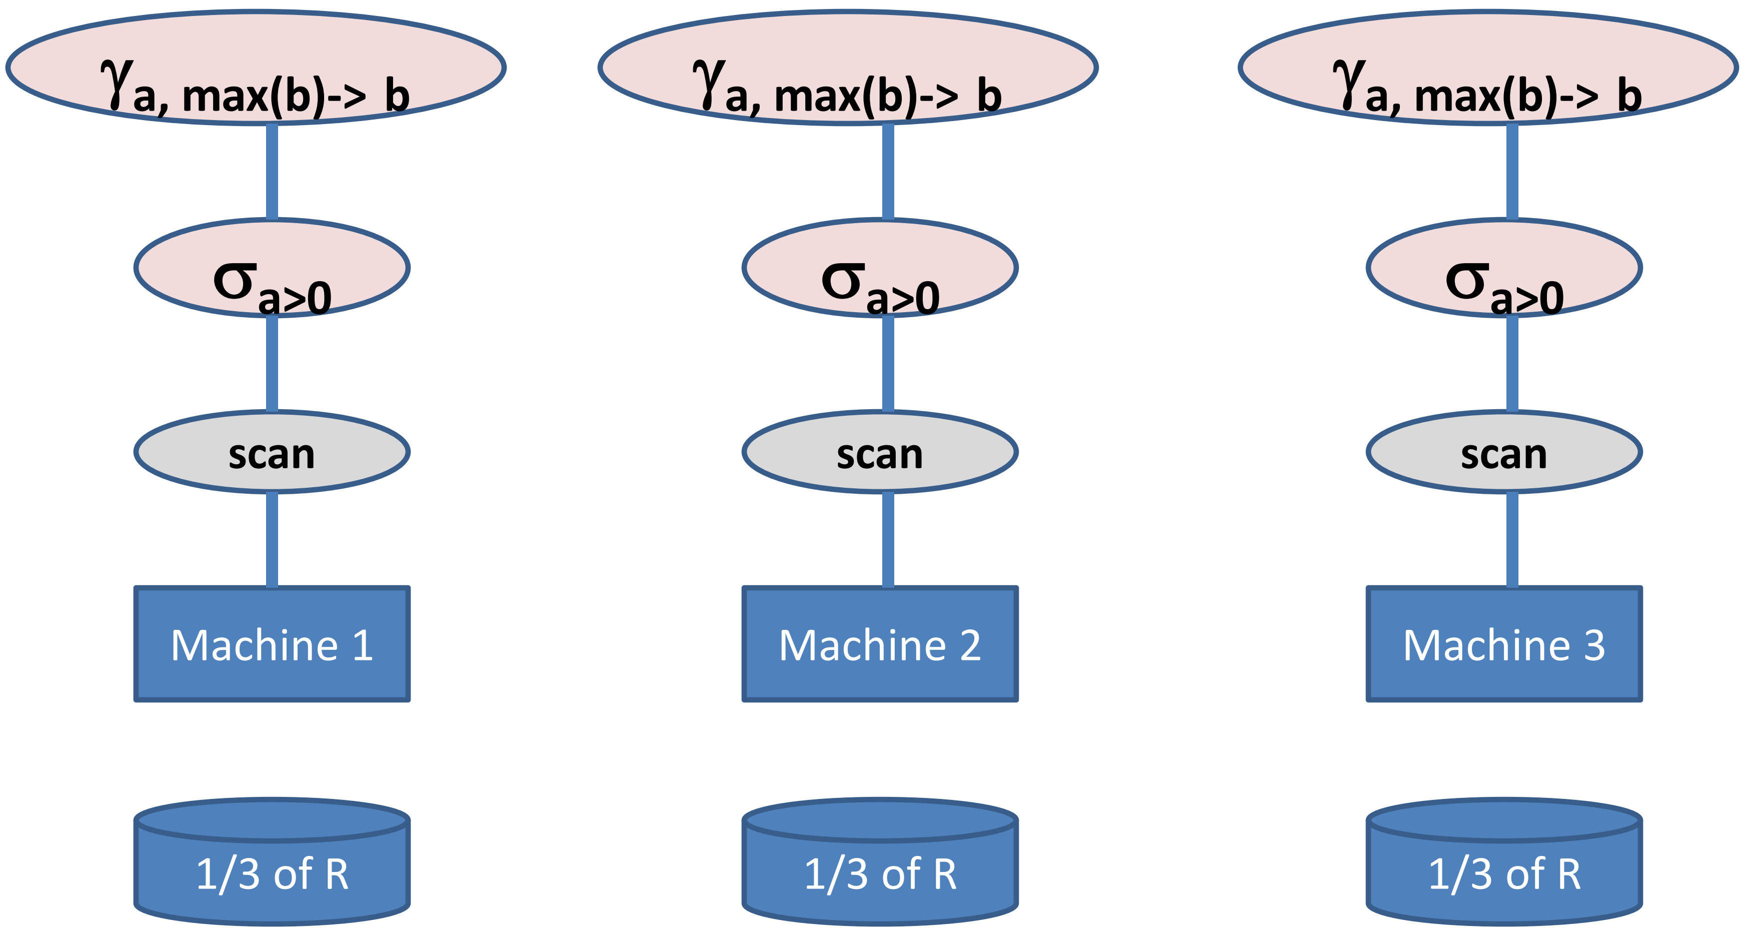
R(a, b)

```
SELECT a, max(b) as topb
FROM R
WHERE a > 0
GROUP BY a
```



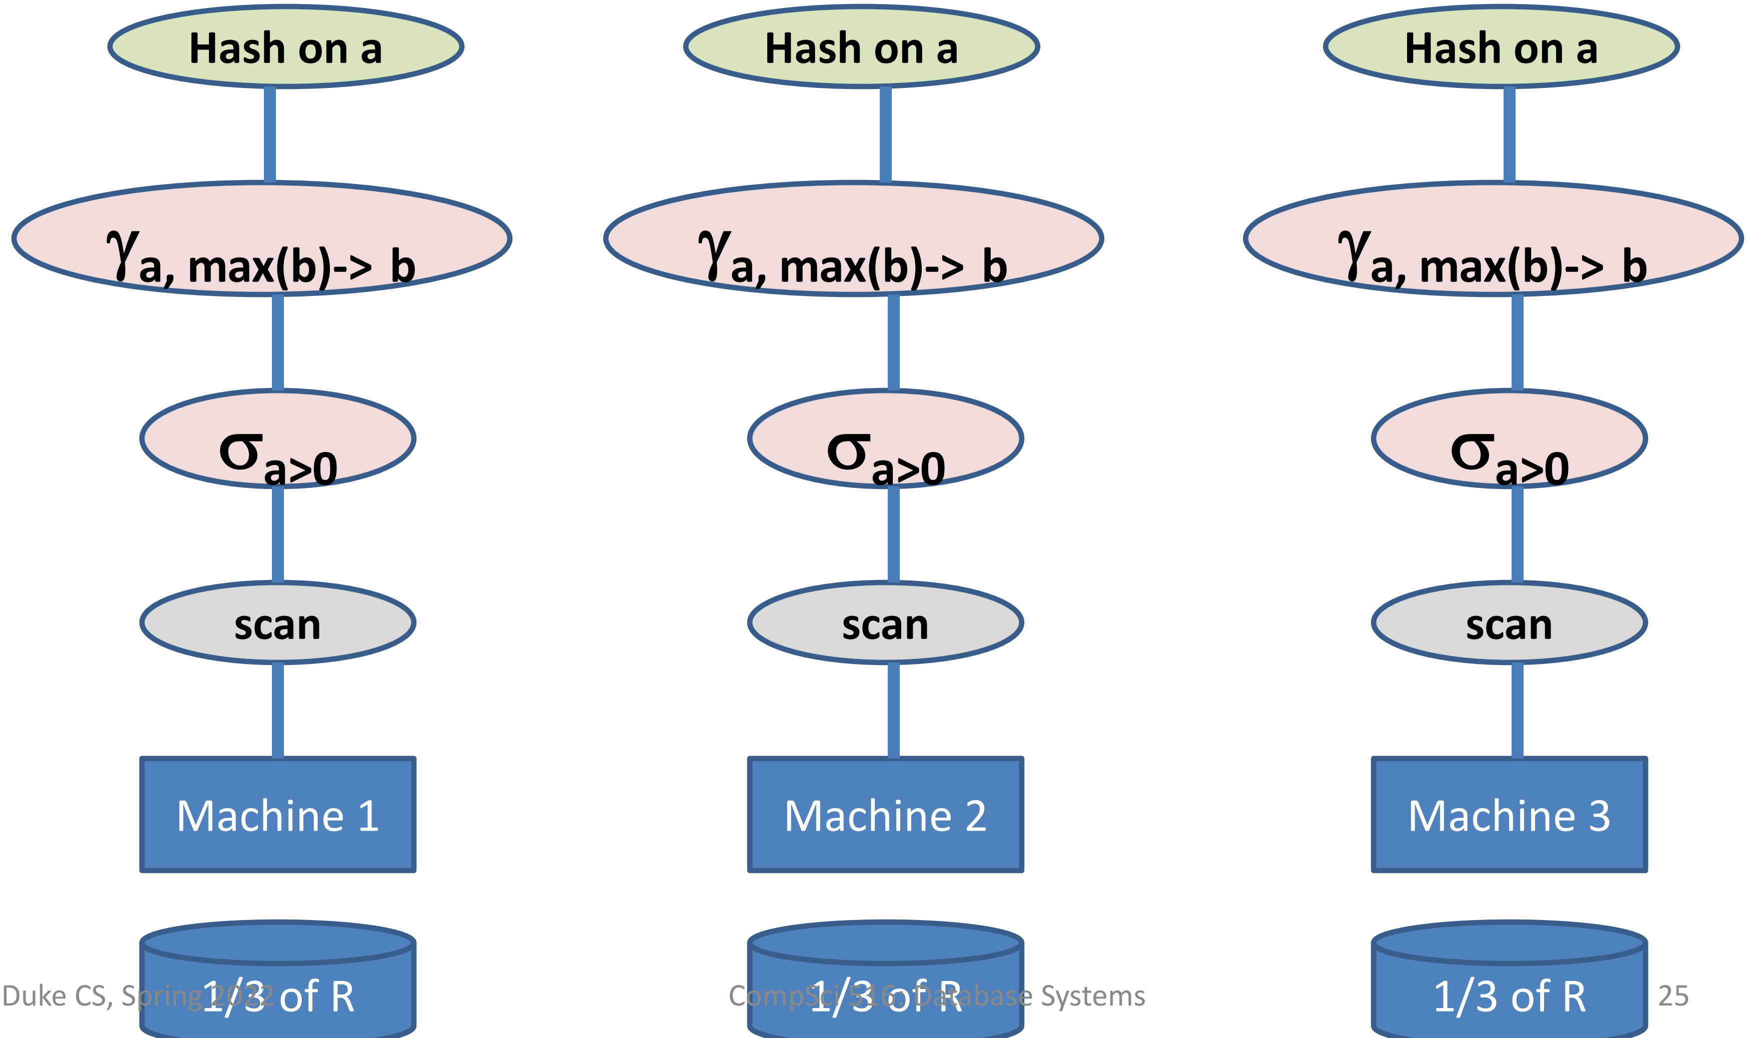
R(a, b)

```
SELECT a, max(b) as topb
FROM R
WHERE a > 0
GROUP BY a
```



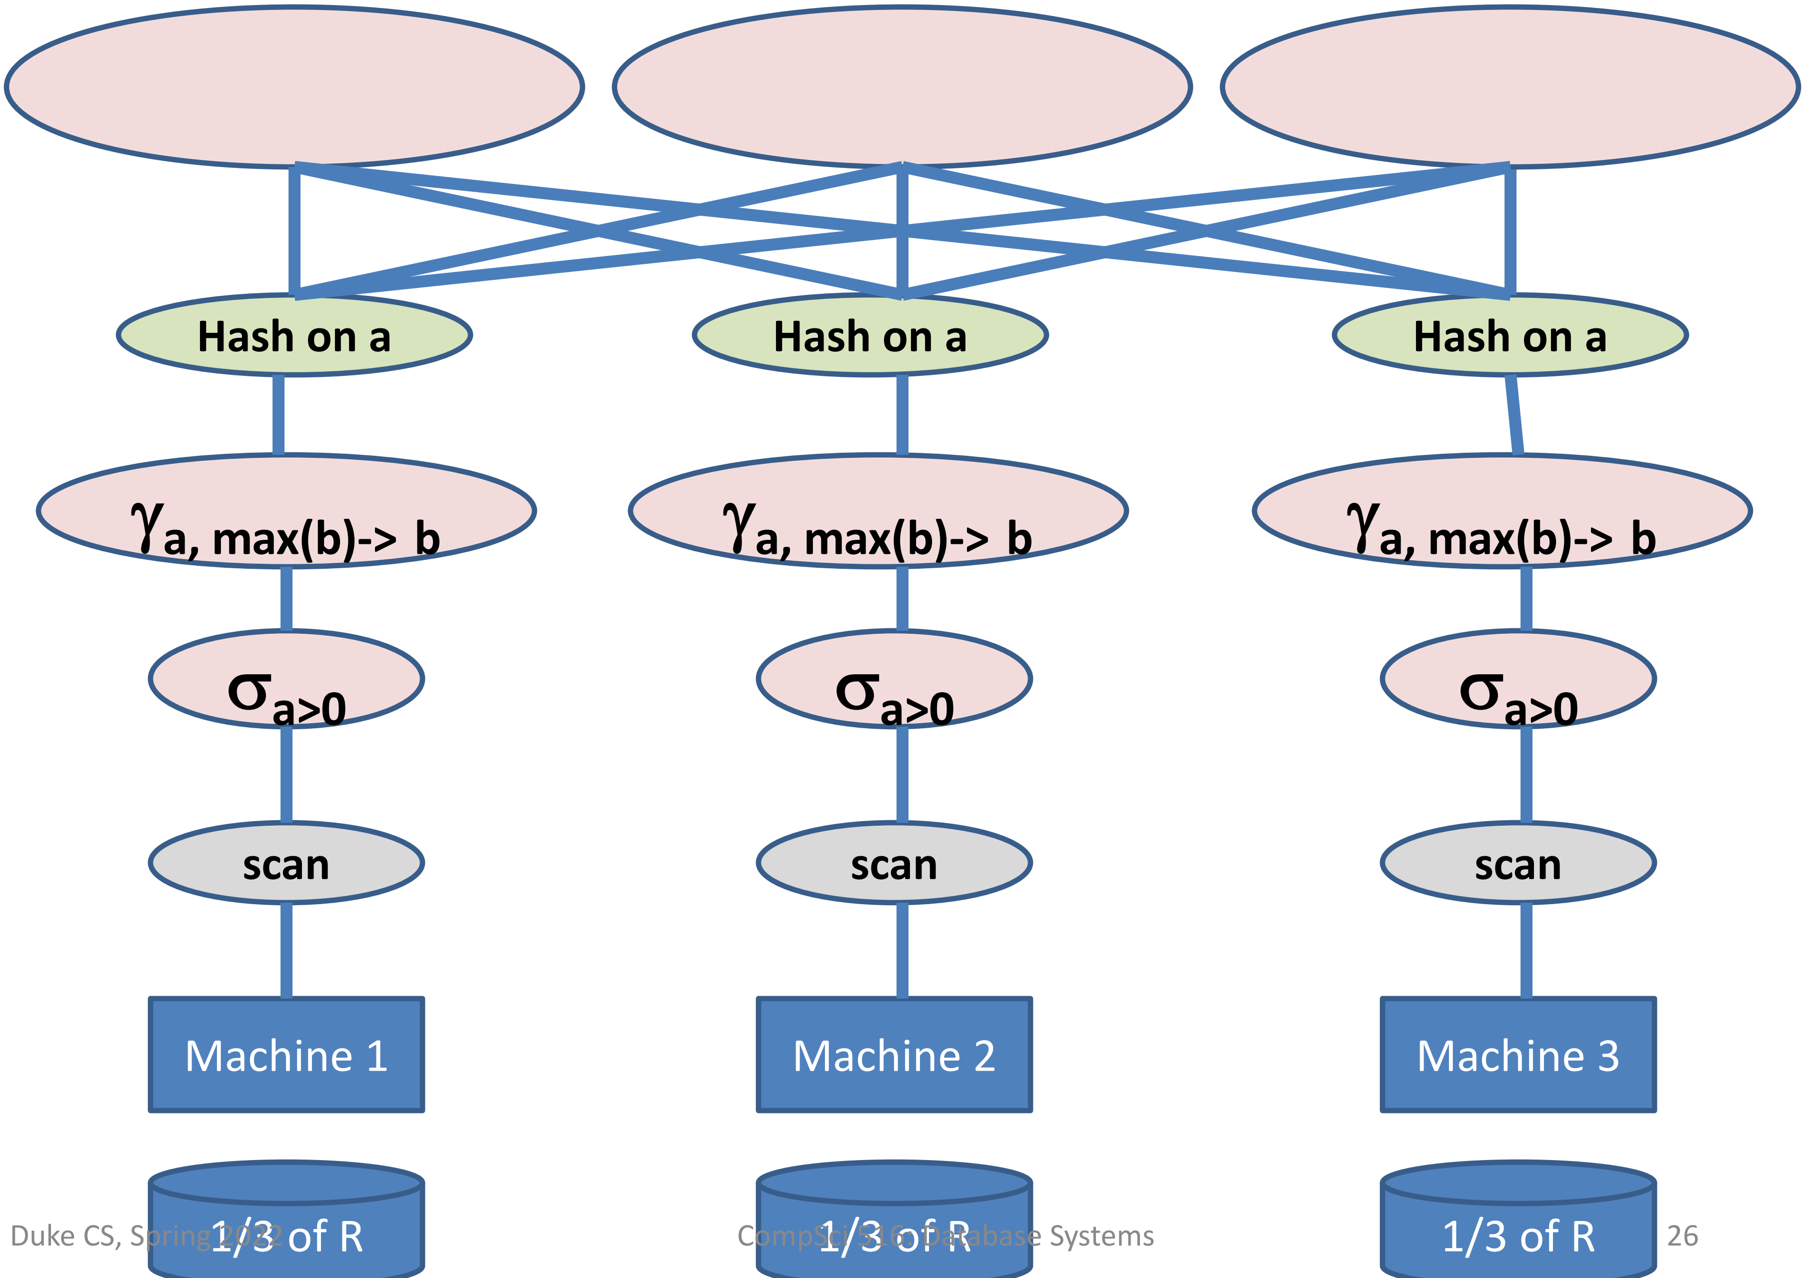
R(a, b)

```
SELECT a, max(b) as topb
FROM R
WHERE a > 0
GROUP BY a
```



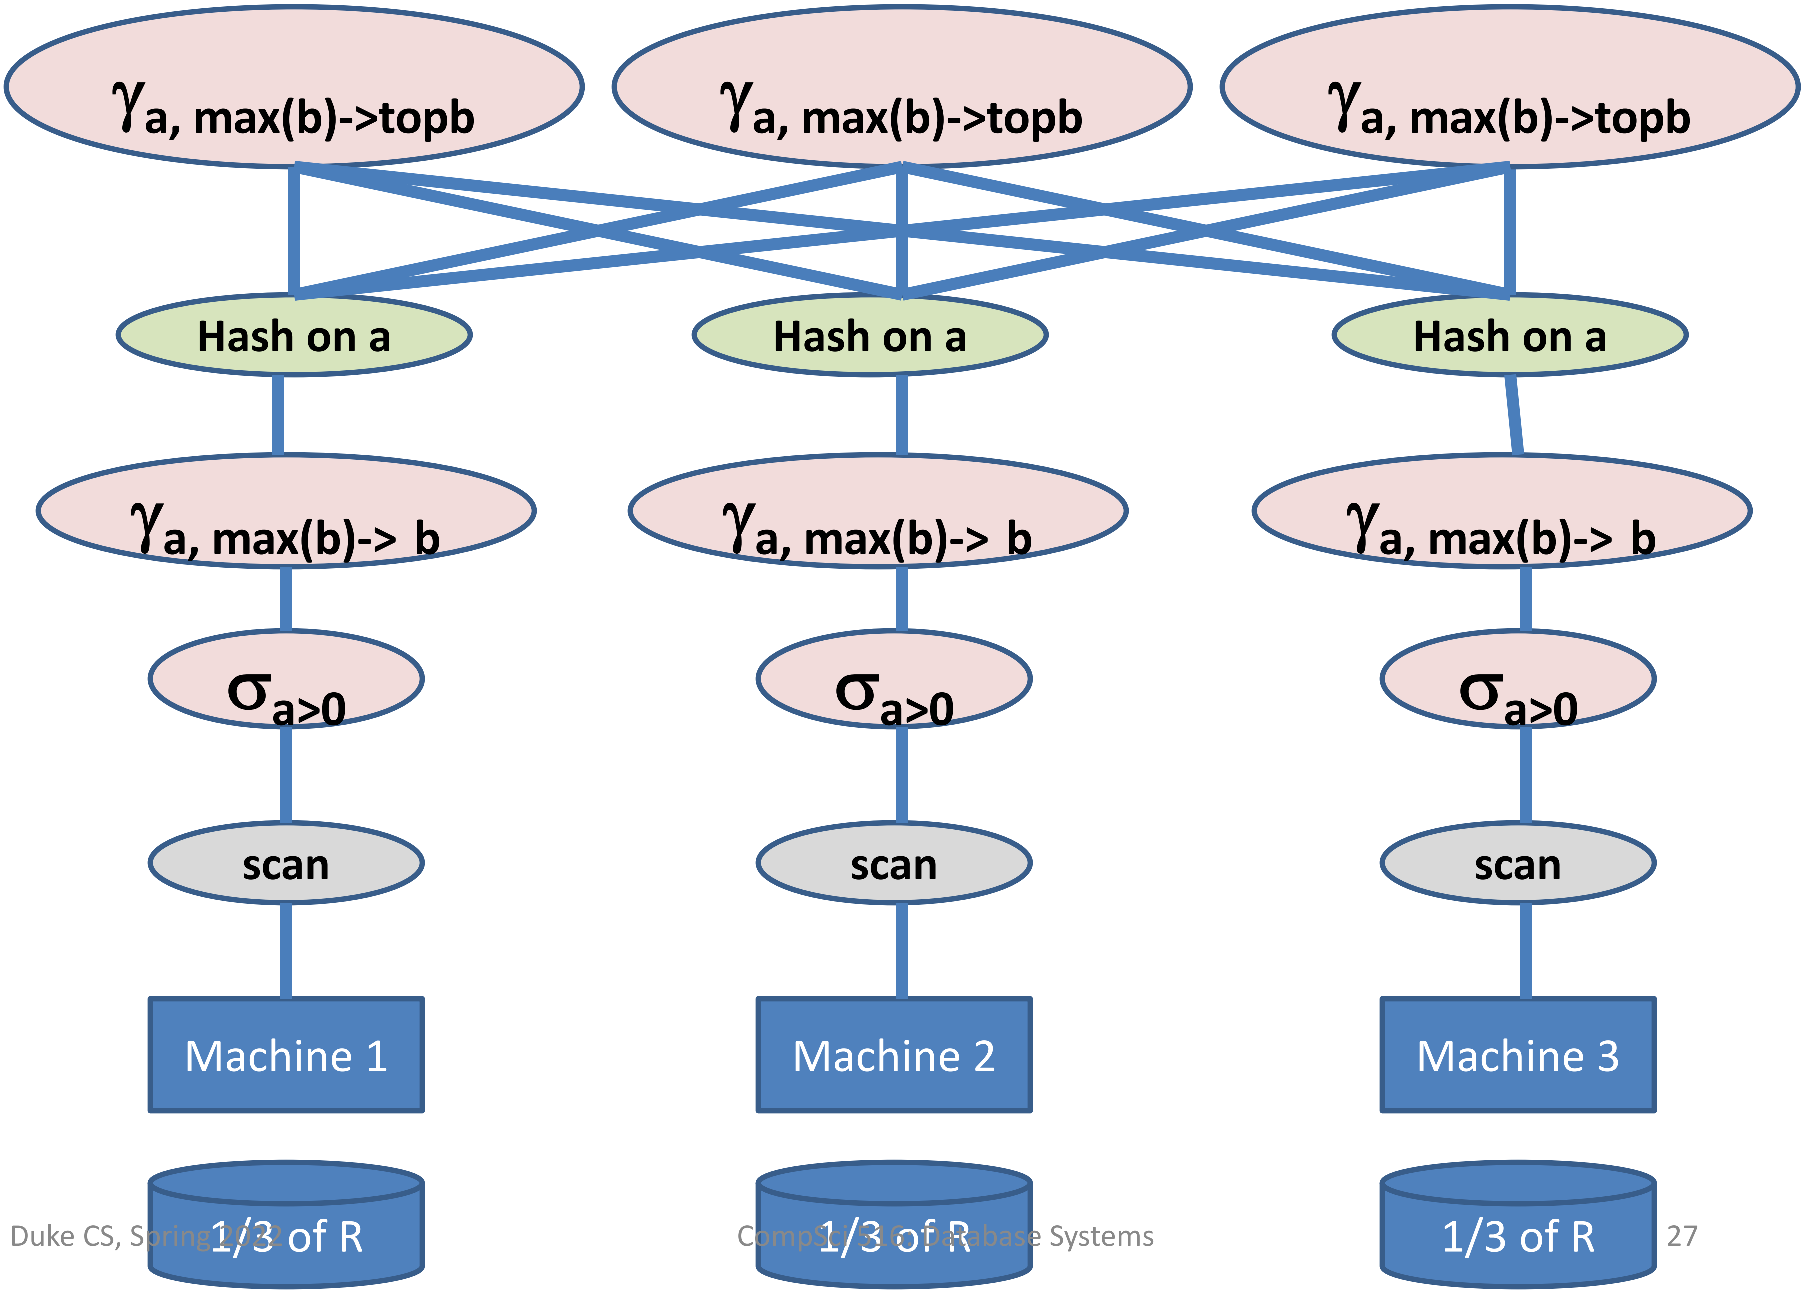
R(a, b)

SELECT a, max(b) as topb FROM R
WHERE a > 0 GROUP BY a



R(a, b)

SELECT a, max(b) as topb FROM R
WHERE a > 0 GROUP BY a



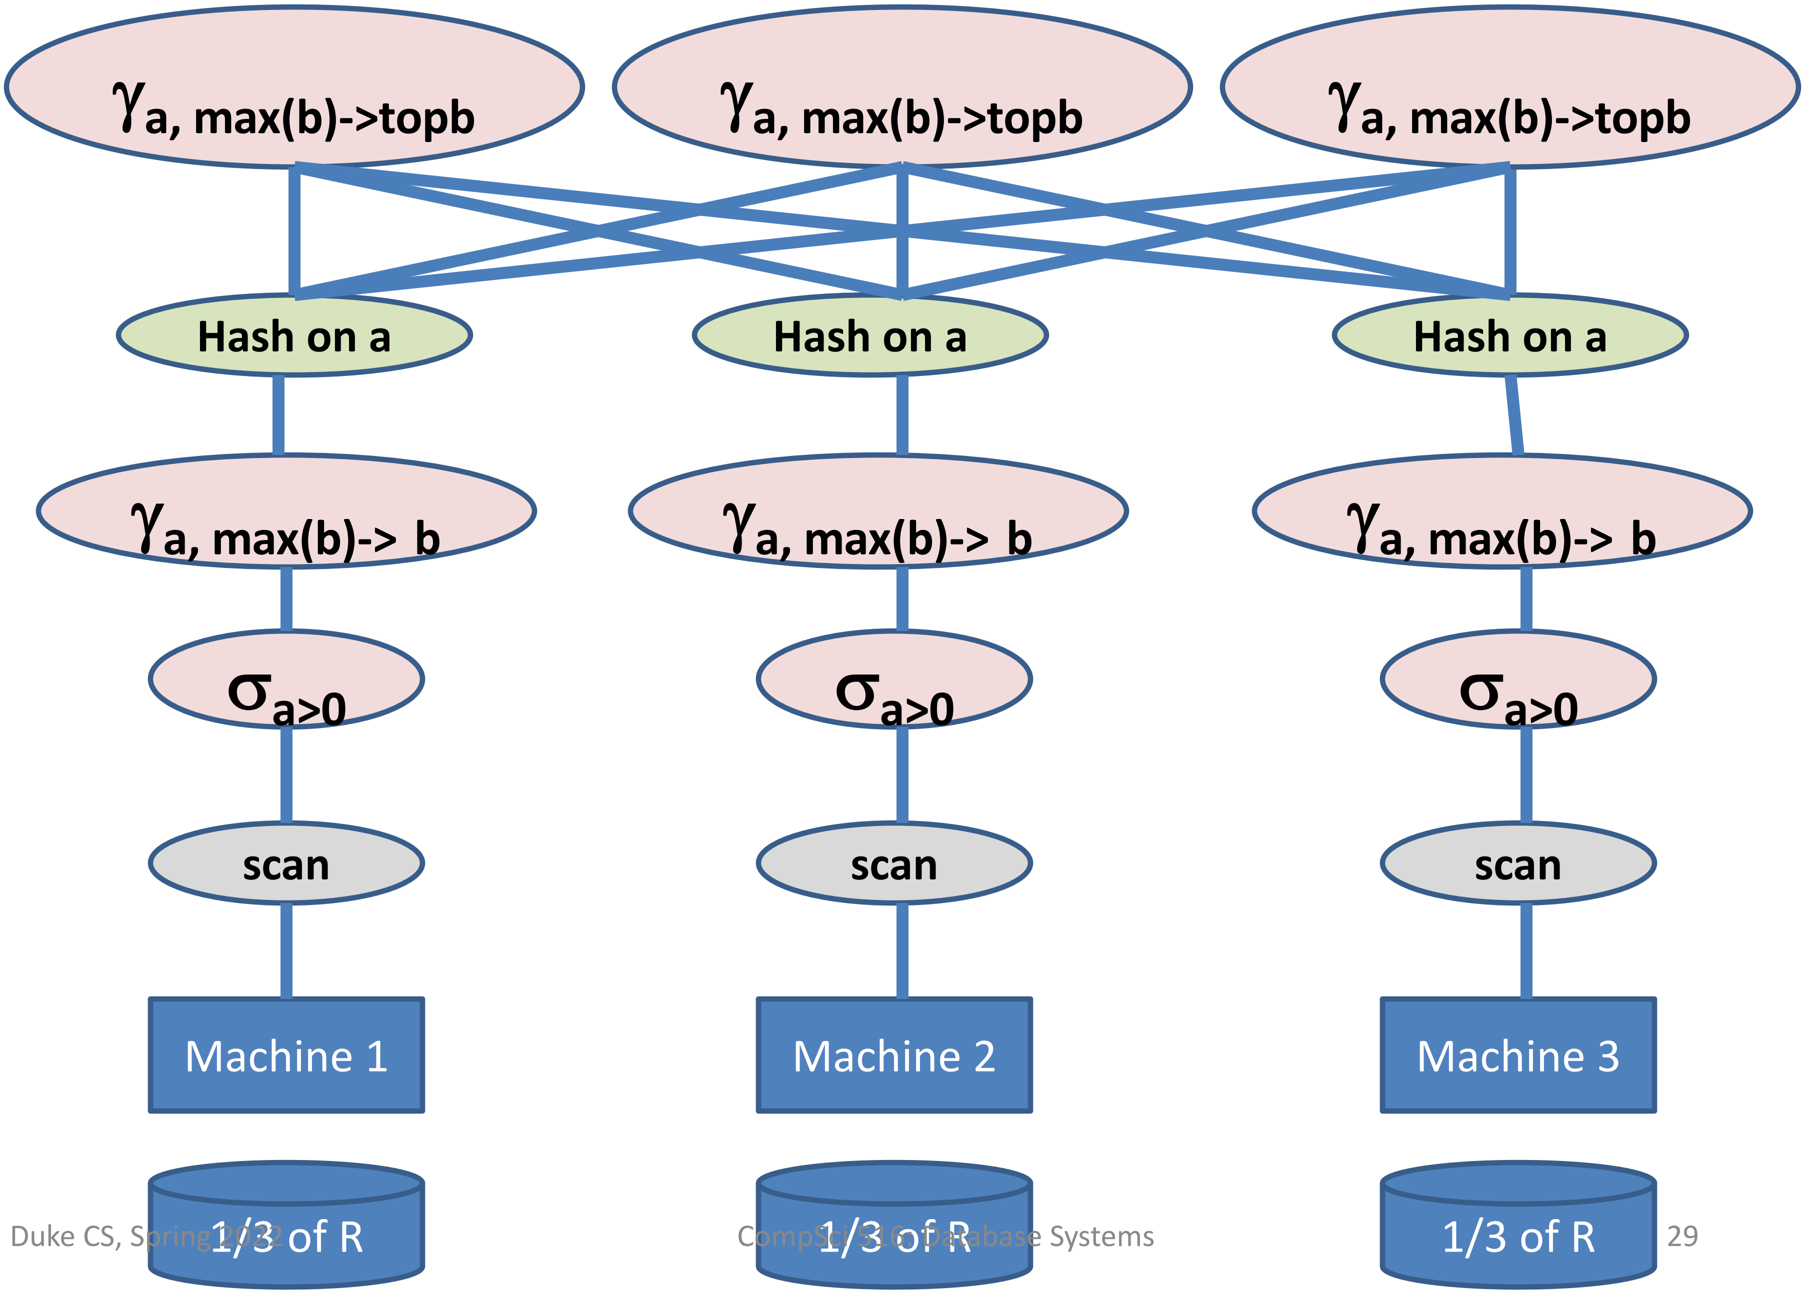
Benefit of hash-partitioning

SELECT a, max(b) as topb
FROM R
WHERE a > 0
GROUP BY a

- What would change if we hash-partitioned R on R.a before executing the same query on the previous parallel DBMS

Prev: block-partition

SELECT a, max(b) as topb FROM R
WHERE a > 0 GROUP BY a



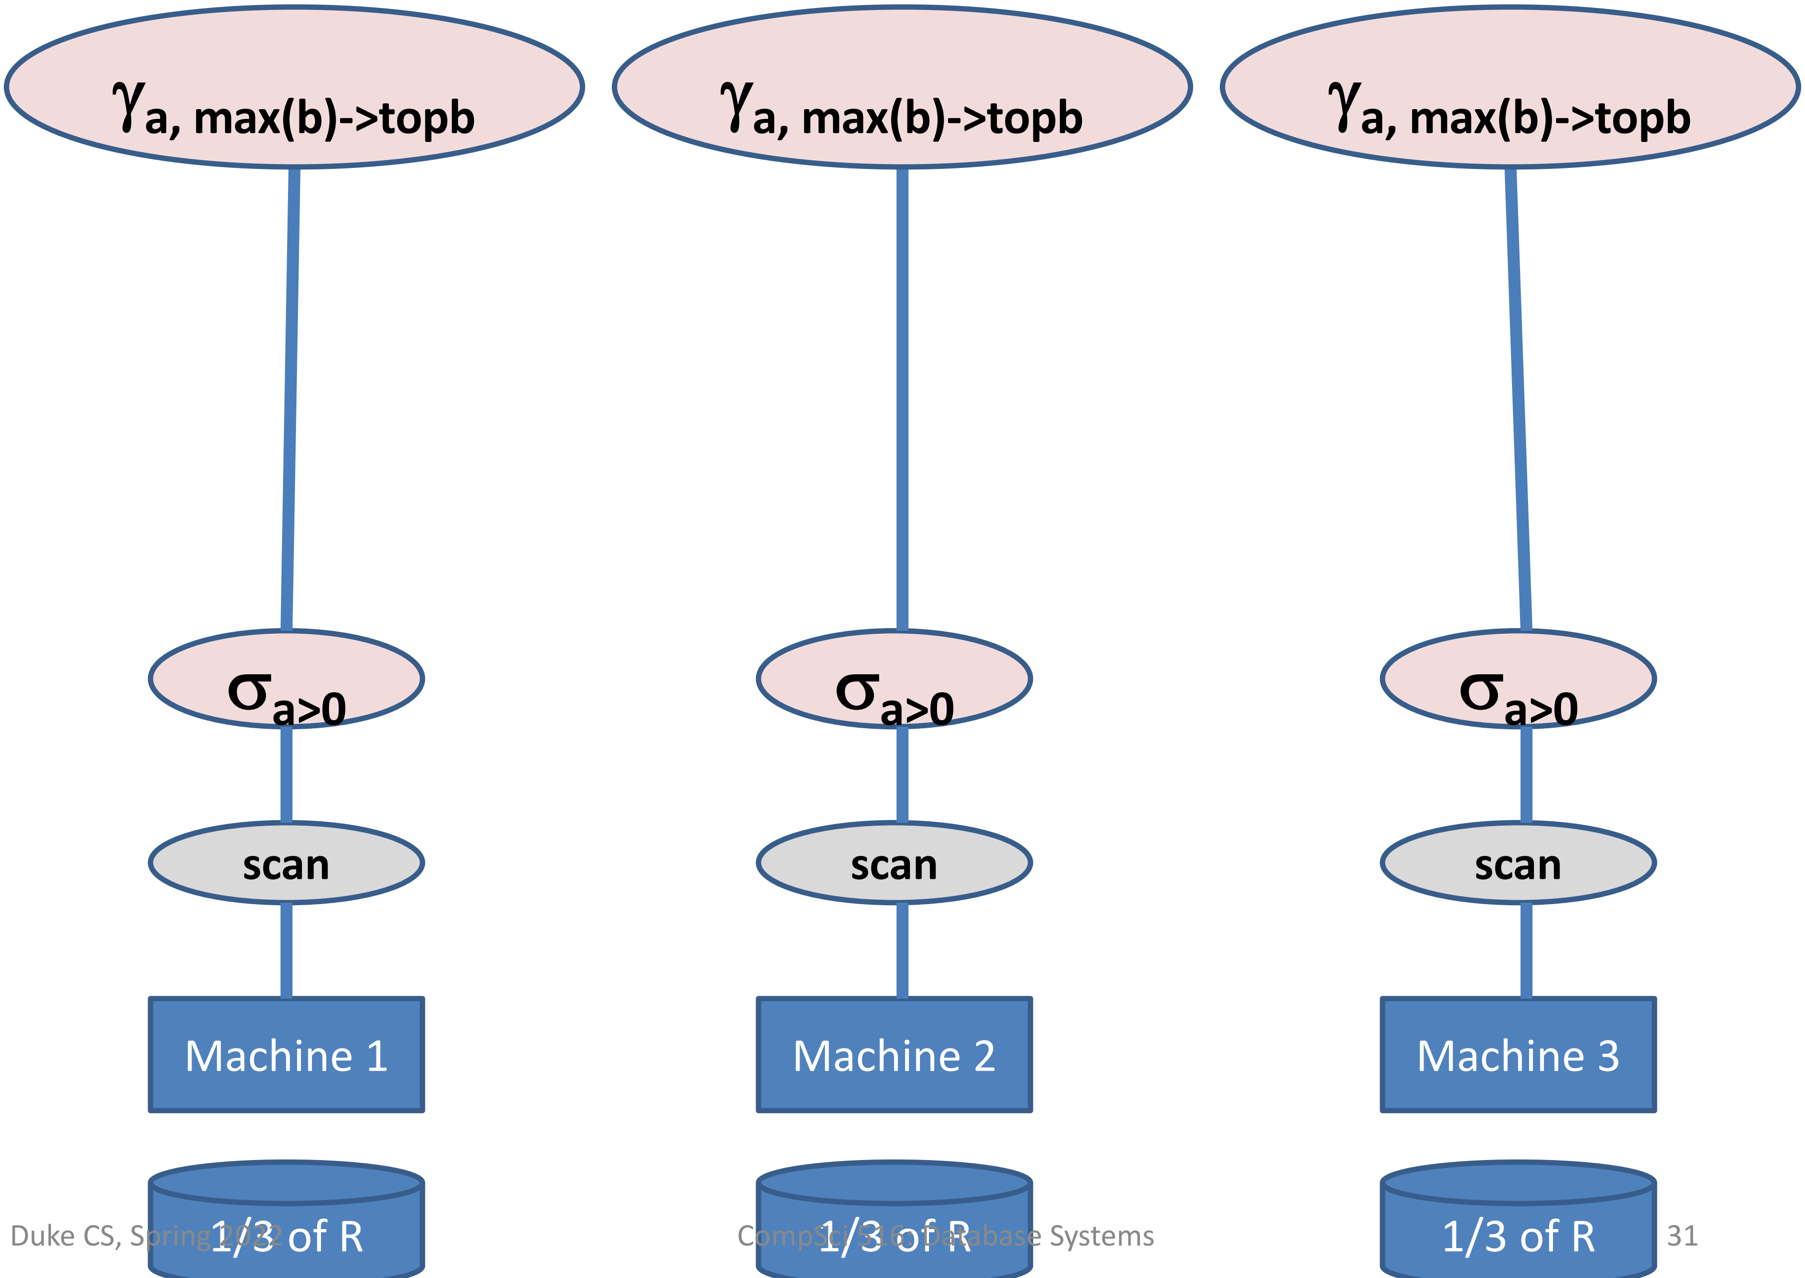
Hash-partition on a for R(a, b)

SELECT a, max(b) as topb
FROM R
WHERE a > 0
GROUP BY a

- It would avoid the data re-shuffling phase
- It would compute the aggregates locally

Hash-partition on a for R(a, b)

SELECT a, max(b) as topb FROM R
WHERE a > 0 GROUP BY a



Column Store (overview)

Row vs. Column Store

- Row store
  - store all attributes of a tuple together
  - storage like “row-major order” in a matrix
- Column store
  - store all rows for an attribute (column) together
  - storage like “column-major order” in a matrix
- e.g.
  - MonetDB, Vertica (earlier, C-store), SAP/Sybase IQ, Google Bigtable (with column groups)

What is a column-store?

+ easy to add/modify a record

- might read in unnecessary data

+ only need to read in relevant data

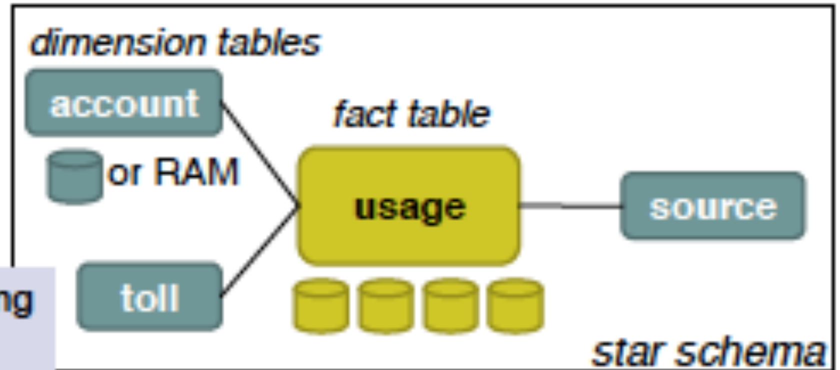
- tuple writes require multiple accesses

=> *suitable for read-mostly, read-intensive, large data repositories*

Ack: Slide from VLDB 2009 tutorial on Column store

Telco Data Warehousing example

- Typical DW installation
- Real-world example



"One Size Fits All? - Part 2: Benchmarking Results" Stonebraker et al. CIDR 2007

QUERY 2

```
SELECT account.account_number,
sum (usage.toll_airtime),
sum (usage.toll_price)
FROM usage, toll, source, account
WHERE usage.toll_id = toll.toll_id
AND usage.source_id = source.source_id
AND usage.account_id = account.account_id
AND toll.type_ind in ('AE'. 'AA')
AND usage.toll_price > 0
AND source.type != 'CIBER'
AND toll.rating_method = 'IS'
AND usage.invoice_date = 20051013
GROUP BY account.account_number
```

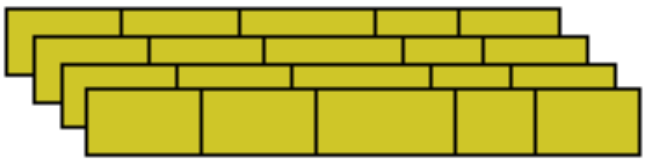
	Column-store	*Row-store*
Query 1	*2.06*	*300*
Query 2	*2.20*	*300*
Query 3	*0.09*	*300*
Query 4	*5.24*	*300*
Query 5	*2.88*	*300*

Why? Three main factors (next slides)

Ack: Slide from VLDB 2009 tutorial on Column store

Telco example explained (1/3): *read efficiency*

row store



read pages containing entire rows

one row = 212 columns!

is this typical? (it depends)

What about vertical partitioning? (it does not work with ad-hoc queries)

column store

read only columns needed

in this example: 7 columns

caveats:

- "select * " not any faster
- clever disk prefetching
- clever tuple reconstruction

Ack: Slide from VLDB 2009 tutorial on Column store

Telco example explained (2/3): *compression efficiency*

- Columns compress better than rows
  - Typical row-store compression ratio 1 : 3
  - Column-store 1 : 10
- Why?
  - Rows contain values from different domains
    => more entropy, difficult to dense-pack
  - Columns exhibit significantly less entropy
  - Examples:

    Male, Female, Female, Female, Male
    1998, 1998, 1999, 1999, 1999, 2000

  - Caveat: CPU cost (use lightweight compression)

Ack: Slide from VLDB 2009 tutorial on Column store

Telco example explained (3/3): *sorting & indexing efficiency*

- Compression and dense-packing free up space
  - Use multiple overlapping column collections
  - Sorted columns compress better
  - Range queries are faster
  - Use sparse clustered indexes
