From practice to theory and back again

In theory there is no difference between theory and practice, but not in practice
- We’ve talked about binary search: requires a sorted vector
  - Much faster than sequential search (how much)
  - Add elements in sorted order or sort vector after adding
- Many sorting algorithms have been well-studied
  - Slower ones are often “good enough” simple to implement
  - Some fast algorithms are better than others
    - Always fast, fast most-of-the-time
    - Good in practice even if flawed theoretically?
- New algorithms still discovered
  - Quick sort in 1960, revised and updated in 1997

Tools for algorithms and programs

- We can time different methods, but how to compare timings?
  - Different on different machines, what about “workload”?
  - Mathematical tools can help analyze/discuss algorithms
- We often want to sort by different criteria
  - Sort CDs by artist, title, genre, length, ...
  - Sort directories/files by size, alphabetically, or by date
  - Object-oriented concepts can help in implementing sorts
- We often want to sort different kinds of vectors: string and int
  - Don’t want to duplicate the code, that leads to errors
  - Generic programming helps, in C++ we use templates

To code or not to code, that is the ...

- Should you call an existing sorting routine or write your own?
  - If you can, don’t rewrite code written and accessible
  - Sometimes you don’t know what to call
  - Sometimes you can’t call the existing library routine
- In C++ there are standard sort functions that can be used with
  built-in arrays and with both vectors and tvectors
  - These are accessible via #include <algorithm>
  - These are robust and fast, call sort(...) or stable_sort(...)
    - Can’t study the code, it’s not legible
- We’ll use sorts in #include “sortall.h”
  - Work only with tvector, nearly as efficient as standard sorts, but code is legible

Finding min element (minfind.cpp)?

- What are differences in functions finding min element?
  - Between int, string, Date, ...? Key feature of elements?
    - Compare using < operator
  - We can use features of language to capture independence
- We can have different versions of function for different array types, with same name but different parameter lists
  - Overloaded function: parameters different so compiler can determine which function to call
  - Still problems, duplicated code, new algorithm means ...
- With function templates we replace duplicated code maintained by programmer with compiler generated code
Creating a function template

```cpp
template <class Type>
Type minfind(const tvector<Type> & v)
// pre: 0 < a.size()
// post: return minimal element in v
{
    Type min = v[0];
    for(k=1; k < numElts; k++)
    { if (v[k] < min) min = v[k];
    }
    return min;
}
```

- When the user calls this code, different versions are compiled

Some template details

- Function templates permit us to write once, use several times for several different types of vector
  - Template function “stamps out” real function
  - Maintenance is saved, code still large (why?)
- What properties must hold for vector elements?
  - Comparable using < operator
  - Elements can be assigned to each other
- Template functions capture property requirements in code
  - Part of generic programming
  - Some languages support this better than others

From practical to theoretical

- We want a notation for discussing differences between algorithms, avoid empirical details at first
  - Empirical studies needed in addition to theoretical studies
  - As we’ll see, theory hides some details, but still works
- Binary search: roughly 10 entries in a 1,000 element vector
  - What is exact relationship? How to capture “roughly”?
  - Compared to sequential/linear search?
- We use O-notation, big-Oh, to capture properties but avoid details
  - \( N^2 \) is the same as \( 13N^2 \) is the same as \( 23N \)
  - \( O(N^2) \), in the limit everything is the same

Running times @ 10^6 instructions/sec

</table>
What does table show? Hide?

- Can we sort a million element vector with selection sort?
  - How can we do this, what's missing in the table?
  - What are hidden constants, low-order terms?
- Can we sort a billion-element vector? Are there other sorts?
  - We'll see quicksort, an efficient (most of the time) method
  - O(N log N), what does this mean?
- Sorting code for different algorithms in sortall.h/sortall.cpp
  - Template functions, prototypes in .h file, implementations in .cpp file, must have both (template isn't code!!)

Templates and function objects

- In a templated sort function vector elements must have certain properties (as noted previously)
  - Comparable using operator <
  - Assignable using operator =
  - Ok for int, string, what about Date? ClockTime?
- What if we want to sort by a different criteria
  - Sort strings by length instead of lexicographically
  - Sort students by age, grade, name, ...
  - Sort stocks by price, shares traded, profit, ...
- We can't change how operator < works
  - Alternative: write sort function that does NOT use <
  - Alternative: encapsulate comparison in parameter, pass it

Function object concept

- To encapsulate comparison (like operator <) in a parameter
  - Need convention for parameter: name and behavior
  - Other issues needed in the sort function, concentrate on being clients of the sort function rather than implementors
- Name convention: class/object has a method named compare
  - Two parameters, the vector elements being compared (might not be just vector elements, any two parameters)
- Behavior convention: compare returns an int
  - zero if elements equal
  - +1 (positive) if first > second
  - -1 (negative) if first < second

Function object example

class StrLenComp {
    public:
        int compare(const string& a, const string& b) const {
            // post: return -1/+1/0 as a.length() < b.length()
            if (a.length() < b.length()) return -1;
            if (a.length() > b.length()) return 1;
            return 0;
        }
};
// to use this:
StrLenComp scomp;
if (scomp.compare("hello", "goodbye") < 0) …
- We can use this to sort, here's a call:
  - Call of sort: InsertSort(vec, vec.size(), scomp);
Another function object example

- Consider “directory.h” and the class DirEntry
  - DirEntry encapsulates file/directory
  - Methods: Name(), Size(), Path(), GetTime(),...
- To sort using Name() use class below, what about Size()?

```cpp
class DirNameComp
{
    public:
    int compare(const DirEntry& a, const DirEntry& b) const
    // post: return -1/+1/0 as a.length() < b.length()
    { if (a.Name() < b.Name()) return -1;
      if (a.Name() > b.Name()) return 1;
      return 0;
    }
};
```

Filtering and sorting CD data

- Here’s an answer from CD assignment: filter tracks based on closeness to 3:00, how do we change to 10 minutes off?
  - Can’t capture this genericity, look at filter function

```cpp
bool timefilter(const CDtrack& track)
// return true if track is 2:55 to 3:05 in length
{
    ClockTime time = track.length;
    int secs = time.Minutes() * 60 + time.Seconds();
    return abs(secs - 180) <= 5;
}
```

- Templates won’t work, function pointers won’t work
- We need another tool: inheritance

How do function pointers work?

```cpp
typedef bool TrackFilterFunction (const CDtrack& track);
PlayList doFilter(TrackFilterFunction filter, PlayList list)
{
    PlayList newlist;
    for(int k=0; k < list.size(); k++)
    { CDtrack track = list.getTrack(k);
      if (filter(track))
      { newlist.addTrack(track);
      }
    }
    return newlist;
}
```

Inheritance to rescue

- See example for sorting playlists in playpick.cpp
  - We add two sort functions to PlayList class, why two?
  - How does compiler know what Comparer object is?
  - Why is Comparer templated?
  - Here’s a new Comparer, watch out for const!

```cpp
struct NameComp : public Comparer<CDtrack>
{
    int compare(const CDtrack& lhs, const CDtrack& rhs) const
    { if (lhs.name < rhs.name) return -1;
      if (lhs.name > rhs.name) return +1;
      return 0;
    }
};
```
From smarter code to algorithm

- We’ve seen selection sort, other O(N^2) sorts include
  - Insertion sort: better on nearly sorted data, fewer comparisons, potentially more data movements (selection)
  - Bubble sort: dog, dog, dog, don’t use it
- Efficient sorts are trickier to code, but not too complicated
  - Often recursive as we’ll see, use divide and conquer
  - Quicksort and Mergesort are two standard examples
- Mergesort divide and conquer
  - Divide vector in two, sort both halves, merge together
  - Merging is easier because subvectors sorted, why?

Quicksort, an efficient sorting algorithm

- Step one, partition the vector, moving smaller elements left, larger elements right
  - Formally: choose a pivot element, all elements less than pivot moved to the left (of pivot), greater moved right
  - After partition/pivot, sort left half and sort right half

Quicksort details

```cpp
void Quick(tvector<string> & a, int first, int last) // pre: first <= last // piv: a[first] <= ... <= a[list]
{
  int piv;
  if (first < last) // original call is Quick(a,0,a.size()-1);
  {
    piv = Pivot(a,first,last);
    Quick(a,first,piv-1);
    Quick(a,piv+1,last);
  }

  How do we make progress towards base case? What’s a good pivot versus a bad pivot? What changes?
  - What about the code for Pivot?
  - What about type of element in vector?
```

How is Pivot similar to RemoveBozos?

```cpp
int Pivot(tvector<string> & a, int first, int last) // post: returns piv so: k in [first..piv], a[k] <= a[piv] // k in (piv,last]piv, a[piv] < a[k]
{
  int p=first;
  string piv = a[first];
  for(k=first+1;k<=last;k++)
  {
    if (a[k] <= piv) p++;
    Swap(a[k],a[p]);
  }
  Swap(a[p],a[first]);
  return p;
}
```

Partition around a[first], can change this later, why is p initially first?
- What is invariant?
What is complexity?

- We’ve used $O$-notation, (big-Oh) to describe algorithms
  - Binary search is $O(\log n)$
  - Sequential search is $O(n)$
  - Selection sort is $O(n^2)$
  - Quicksort is $O(n \log n)$

- What do these measures tell us about “real” performance?
  - When is selection sort better than quicksort?
  - What are the advantages of sequential search?

- Describing the complexity of algorithms rather than implementations is important and essential
  - Empirical validation of theory is important too

Do it fast, do it slow, can we do it at all?

- Some problems can be solved quickly using a computer
  - Searching a sorted list

- Some problems can be solved, but it takes a long time
  - Towers of Hanoi

- Some problems can be solved, we don’t know how quickly
  - Traveling salesperson, optimal class scheduling

- Some problems can’t be solved at all using a computer
  - The halting problem, first shown by Alan Turing

- The halting problem: can we write one program used to determine if an arbitrary program (any program) stops?
  - One program that reads other programs, must work for every program being checked, computability

What is computer science?

- What is a computation?
  - Can formulate this precisely using mathematics
  - Can say “anything a computer can compute”
  - Study both theoretical and empirical formulations, build machines as well as theoretical models

- How do we build machines and the software that runs them?
  - Hardware: gates, circuits, chips, cache, memory, disk, ...
  - Software: operating systems, applications, programs

- Art, Science, Engineering
  - How do we get better at programming and dealing with abstractions
  - What is hard about programming?
