CompSci 101
Introduction to Computer Science

December 5, 2017
Prof. Rodger
Announcements

• Regrades Exam 2 – submit by Thursday, Dec 7
• Regrades for Asg 1-5, APT 1-7 by Dec 8
  – Check your grades! RQ too!
• Assign 8 due today, last late day Dec 8!
• APT 8 due Thursday, Dec 7, last late day, Dec 10!
• Assign 9 – due Dec 11, no late after this date
• Final Exam:
  – Sec 01 Thur, Dec 14, 9am, LSRC B101
  – Sec 02 Sat, Dec 16, 2pm, LSRC B101
  – Get accommodations? Fill out for Final Exam
Calculate Your Grade

- From “About” tab on course web page

<table>
<thead>
<tr>
<th>Activity</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Labs</td>

<tr>
<td>final exam</td>
<td>25%</td>
</tr>
</tbody>
</table>
More on Grades

- Lecture – ignore the first two weeks (drop/add period), plus drop 4 points
- Reading Quizzes – will drop 30 points
  - Check your grades to make sure they copied over – fill out duke oit help form if they are wrong
- Lab – drop 6 points (each lab is 4 pts)
  - 44 pts total – 38 pts is 100%
  - Lab 11 covers two new topics!
More Announcements

• Be a UTA for CompSci 101
  – Rewarding and Learning Experience
  – Apply: see link in Sakai announcement

• Today:
  – Finish from last time
  – Why are dictionaries so fast?
  – More on Recursion, Regex
  – More on Sorting and analyzing it
Answer Questions
bit.ly/101f17-1205-1

SortByFreqs APT
Sort items by their frequency, break ties alphabetically

data = ["apple", "pear", "cherry", "apple", "pear", "apple", "banana"]

Returns: ["apple", "pear", "banana", "cherry"]
Review Recursion and Regex
bit.ly/101f17-1205-2
Dictionary Comprehension

• List comprehension - builds a new list
• Dictionary comprehension - builds a new dictionary

• Format
  
  \[
  d = \{ \text{key: value for key in somelist if } \ldots \} 
  \]

  :
Example: From Exam 2  Sec 01—dict of clubs to list of tuples

```python
def dictClubsToMeetings(data):
    d = {}
    for item in data:
        club = item[0]
        person = item[1]
        meetings = int(item[3])
        if club not in d:
            d[club] = []
        d[club].append(((person, meetings))
    return d
```

```python
def dictClubsToMeetings(data):
    d = {item[0]:[] for item in data}
    for item in data:
        club = item[0]
        person = item[1]
        meetings = int(item[3])
        d[club].append(((person, meetings))
    return d
```
Example: From Exam 2  Sec 02–
dict of names to list of tuples

```python
def dictNamesToMeetings(data):
    d = {}
    for item in data:
        club = item[0]
        person = item[1]
        meetings = int(item[3])
        if person not in d:
            d[person] = []
        d[person].append(((club, meetings))
    return d
```

```python
def dictNamesToMeetings(data):
    d = {item[1]:[] for item in data}
    for item in data:
        club = item[0]
        person = item[1]
        meetings = int(item[3])
        d[person].append(((club, meetings))
    return d
```
Why are dictionaries so fast?

• They use a technique called hashing
• Each key is converted to hopefully a unique storage location address.
• Then each key’s value can be found quickly by indexing to that location

• A dictionary may really be a list underneath, its how you use the list…. 
Simple Example Hashing

Want a mapping of Soc Sec Num to Names

• Duke's ACM Chapter wants to be able to quickly find out info about its members. Also add, delete and update members. Doesn't need members sorted.

  267-89-5431  John Smith
  703-25-6141  Jack Adams
  319-86-2115  Betty Harris
  476-82-5120  Rose Black

• Hash Table size is 0 to 10
• Possible Hash Function: \( H(\text{ssn}) = \text{last 2 digits mod 11} \)
Have a list of size 11 from 0 to 10

- Insert these into the list
- Insert as (key, value) tuple
  (267-89-5431, John Smith)
  (in example, only showing name)
Hashing, dictionaries
bit.ly/101f17-1205-3
Review:
Sorting with itemgetter

• We can write: import operator
  – Then use key=operator.itemgetter(…)

• We can write: from operator import itemgetter
  – Then use key=itemgetter(…)

Review Example with itemgetter

• Because sort is stable sort first on tie-breaker, then that order is fixed since stable

```python
a0 = sorted(data, key=operator.itemgetter(0))
a1 = sorted(a0, key=operator.itemgetter(2))
a2 = sorted(a1, key=operator.itemgetter(1))
data
[('f', 2, 0), ('c', 2, 5), ('b', 3, 0), ('e', 1, 4), ('a', 2, 0), ('d', 2, 4)]
a0
[('a', 2, 0), ('b', 3, 0), ('c', 2, 5), ('d', 2, 4), ('e', 1, 4), ('f', 2, 0)]
```
Two-pass (or more) sorting

```python
a0 = sorted(data, key=operator.itemgetter(0))
a1 = sorted(a0, key=operator.itemgetter(2))
a2 = sorted(a1, key=operator.itemgetter(1))
a0
[('a', 2, 0), ('b', 3, 0), ('c', 2, 5),
 ('d', 2, 4), ('e', 1, 4), ('f', 2, 0)]
a1
[('a', 2, 0), ('b', 3, 0), ('f', 2, 0),
 ('d', 2, 4), ('e', 1, 4), ('c', 2, 5)]
a2
[('e', 1, 4), ('a', 2, 0), ('f', 2, 0),
 ('d', 2, 4), ('c', 2, 5), ('b', 3, 0)]
```
Stable, Stability

• What does the search query 'stable sort' show us?
  – Image search explained
  – First shape, then color: for equal colors?
Stable sorting: respect re-order

- Women before men …
  - First sort by height, then sort by gender
Answer Questions
bit.ly/101f17-1205-4

MedalTable APT

Sort items by their frequency, then sorted in frequencies.

["ITA JPN AUS", "KOR TPE UKR", "KOR KOR GBR", "KOR CHN TPE"]

Returns:
[ "KOR 3 1 0", "ITA 1 0 0", "TPE 0 1 1", "CHN 0 1 0", "JPN 0 1 0", "AUS 0 0 1", "GBR 0 0 1", "UKR 0 0 1"
]
Sorting

• In python:
  – alist = [8, 5, 2, 3, 1, 6, 4]
  – alist.sort() OR result = sorted(alist)
  – Now alist OR result is [1, 2, 3, 4, 5, 6, 8]

• How does one sort elements in order? How does “sort” work?
Selection Sort

- Sort a list of numbers.
- Idea:
  - Repeat til sorted
    - Find the smallest element in part of list not sorted
    - Put it where it belongs in sorted order.
      - Swap it with the element where it should be
- Sort example

| Sorted, won’t move final position | ??? |
Example: Selection Sort

- Sort the list of numbers using Selection Sort.
- The body of the loop is one pass.
- Show the elements after each pass.
- 9, 5, 4, 1, 3, 6
Selection Sort

• Sort the list of numbers using Selection Sort.
• The body of the loop is one pass.
• Show the elements after each pass.
• 6, 4, 9, 7, 1, 3
def selectsort(data):
    for i in range(len(data)):
        mindex = minindex(i)
        # swap elements at indexes i and mindex
        tmp = data[i]
        data[i] = data[mindex]
        data[mindex] = tmp
Bubble Sort

• Sort a list of numbers.
• Idea:
  – Repeat til sorted
    • Compare all adjacent pairs, one at a time. If out of order then swap them
• Sort example

<table>
<thead>
<tr>
<th>???</th>
<th>Sorted, won’t move final position</th>
</tr>
</thead>
</table>
Bubble Sort
bit.ly/101f17-1205-6

• Sort the list of numbers using BubbleSort.
• The body of the loop is one pass.
• Show the elements after each pass.
• [6, 4, 9, 7, 1, 3]
Bubble Sort – red area sorted

6  4  9  7  1  3 - compare, swap
4  6  9  7  1  3 - compare, no swap
4  6  9  7  1  3 - compare, swap
4  6  7  9  1  3 - compare, swap
4  6  7  1  9  3 - compare, swap
4  6  7  1  3  9 - end of 1\textsuperscript{st} pass
4  6  7  1  3  9
