Number Theory

• Is 73512 divisible by 9?

7 + 3 + 5 + 1 + 2 = 18, 1 + 8 = 9
73512 / 9 = 8168

• A number is only divisible by 9 if its digits sum to 9 or a multiple of 9

Number Theory Example

• Consider all the odd numbers that don’t end in 5
  – 1, 3, 7, 9, 11, 13, 17, 19, 21, 23, ..., 2009, ...
  – Each of them divides evenly into a number that consists only of 9’s
  – 1, 3, 9
  – 7, 11, 13
  – 2009
  – It should divide some number that has all 9’s. Which one? Consider the first 2010 numbers of 9’s only.
  – 9, 99, 999, 9999, 99999, ..., 9999...999 (2010 9’s)

Number Theory Example (cont)

• Consider 2010 different numbers with all 9’s
  – 9, 99, 999, 9999, 99999, ..., 9999...999 (2010 9’s)
• Divide each by 2009
i 9's = 2009q + r
j 9's = 2009p + r

Properties of Divisibility

Theorem 1: Let a, b, and c be integers, where a ≠ 0.
   i. If a | b and a | c, then a | (b + c);
   ii. If a | b, then a | bc for all integers c;
   iii. If a | b and b | c, then a | c.
Proof: (i) Suppose a | b and a | c

Corollary: If a, b, and c be integers, where a ≠ 0, such that a | b and a | c, then a | mb + nc whenever m and n are integers.

Chap. 4.1 - Division

Definition: If a and b are integers with a ≠ 0, then a divides b if there exists an integer c such that b = ac.
   – When a divides b we say that a is a factor or divisor of b and that b is a multiple of a.
   – The notation a | b denotes that a divides b.
   – If a | b, then b/a is an integer.
   – If a does not divide b, we write a ∤ b.
Example: Determine whether 4 | 9 and whether 4 | 12.

Division Algorithm

Division Algorithm: If a is an integer and d a positive integer, then there are unique integers q and r, with 0 ≤ r < d, such that a = dq + r
   • d is called the divisor.
   • a is called the dividend.
   • q is called the quotient.
   • r is called the remainder.

Definitions of Functions div and mod

q = a div d
r = a mod d
Examples

• What are the quotient and remainder when 103 is divided by 11?

• What are the quotient and remainder when $-11$ is divided by 3?

Congruence Relation

Definition: If $a$ and $b$ are integers and $m$ is a positive integer, then $a$ is congruent to $b$ modulo $m$ if $m$ divides $a - b$.

- The notation $a \equiv b \pmod{m}$ says that $a$ is congruent to $b$ modulo $m$.
- We say that $a \equiv b \pmod{m}$ is a congruence and that $m$ is its modulus.
- Two integers are congruent mod $m$ if and only if they have the same remainder when divided by $m$.
- If $a$ is not congruent to $b$ modulo $m$, we write $a \not\equiv b \pmod{m}$.

Example: Determine whether 19 is congruent to 3 modulo 4 and whether 26 and 16 are congruent modulo 6.

Solution:

More on Congruences

**Theorem 4:** Let $m$ be a positive integer. The integers $a$ and $b$ are congruent modulo $m$ if and only if there is an integer $k$ such that $a = b + km$.

**Proof:**

The Relationship between (mod $m$) and mod $m$ Notations

- The use of “mod” in $a \equiv b \pmod{m}$ and $a \mod m = b$ are different.
  - $a \equiv b \pmod{m}$ is a relation on the set of integers.
  - In $a \mod m = b$, the notation mod denotes a function.
- The relationship between these notations is made clear in this theorem.
- **Theorem 3:** Let $a$ and $b$ be integers, and let $m$ be a positive integer. Then $a \equiv b \pmod{m}$ if and only if $a \mod m = b \mod m$. (Proof in the exercises)
**Congruences of Sums and Products**

**Theorem 5:** Let m be a positive integer. If \( a \equiv b \pmod{m} \) and \( c \equiv d \pmod{m} \), then
\[
 a + c \equiv b + d \pmod{m} \quad \text{and} \quad ac \equiv bd \pmod{m}
\]

**Proof:**
- Because \( a \equiv b \pmod{m} \) and \( c \equiv d \pmod{m} \), by Theorem 4 there are integers \( s \) and \( t \) with \( b = a + sm \) and \( d = c + tm \).
- Therefore,
  - \( b + d = (a + sm) + (c + tm) = (a + c) + m(s + t) \)
  - \( bd = (a + sm)(c + tm) = ac + m(at + cs + tm) \)

Hence, \( a + c \equiv b + d \pmod{m} \) and \( ac \equiv bd \pmod{m} \).

**Example:** Because \( 3 \equiv 2 \pmod{5} \) and \( 7 \equiv 1 \pmod{5} \), it follows from Theorem 5 that
\[
3 + 7 \equiv 2 + 1 \equiv 0 \pmod{5}
\]

**Algebraic Manipulation of Congruences**

- Multiplying both sides of a valid congruence by an integer preserves validity.
  If \( a \equiv b \pmod{m} \) holds then \( c \cdot a \equiv c \cdot b \pmod{m} \), where \( c \) is any integer, holds by Theorem 5 with \( d = c \).
- Adding an integer to both sides of a valid congruence preserves validity.
  If \( a \equiv b \pmod{m} \) holds then \( c + a \equiv c + b \pmod{m} \), where \( c \) is any integer, holds by Theorem 5 with \( d = c \).
- Dividing a congruence by an integer does not always produce a valid congruence.

**Example:** The congruence \( 14 \equiv 8 \pmod{6} \) holds. But dividing both sides by 2 does not produce a valid congruence since \( 14/2 = 7 \) and \( 8/2 = 4 \), but \( 7 \not\equiv 4 \pmod{6} \).

See Section 4.3 for conditions when division is ok.

**Computing the mod m Function of Products and Sums**

- We use the following corollary to Theorem 5 to compute the remainder of the product or sum of two integers when divided by \( m \) from the remainders when each is divided by \( m \).

**Corollary:** Let \( m \) be a positive integer and let \( a \) and \( b \) be integers. Then
\[
(a + b) \pmod{m} = ((a \pmod{m}) + (b \pmod{m})) \pmod{m}
\]
and
\[
ab \pmod{m} = ((a \pmod{m})(b \pmod{m})) \pmod{m}.
\]
(proof in text)

**Arithmetic Modulo m**

**Definitions:** Let \( \mathbb{Z}_m \) be the set of nonnegative integers less than \( m \): \( \{0,1, \ldots, m-1\} \)

- The operation \( +_m \) is defined as \( a +_m b = (a + b) \pmod{m} \). This is addition modulo \( m \).
- The operation \( \cdot_m \) is defined as \( a \cdot_m b = (a \cdot b) \pmod{m} \). This is multiplication modulo \( m \).
- Using these operations is said to be doing arithmetic modulo \( m \).

**Example:** Find \( 7 +_{11} 9 \) and \( 7 \cdot_{11} 9 \).

**Solution:** Using the definitions above:
Arithmetic Modulo $m$

- The operations $+_{m}$ and $\cdot_{m}$ satisfy many of the same properties as ordinary addition and multiplication.

  - **Closure:** If $a$ and $b$ belong to $\mathbb{Z}_m$, then $a +_{m} b$ and $a \cdot_{m} b$ belong to $\mathbb{Z}_m$.

  - **Associativity:** If $a$, $b$, and $c$ belong to $\mathbb{Z}_m$, then $(a +_{m} b) +_{m} c = a +_{m} (b +_{m} c)$ and $(a \cdot_{m} b) \cdot_{m} c = a \cdot_{m} (b \cdot_{m} c)$.

  - **Commutativity:** If $a$ and $b$ belong to $\mathbb{Z}_m$, then $a +_{m} b = b +_{m} a$ and $a \cdot_{m} b = b \cdot_{m} a$.

  - **Identity elements:** The elements 0 and 1 are identity elements for addition and multiplication modulo $m$, respectively.
    - If $a$ belongs to $\mathbb{Z}_m$, then $a +_{m} 0 = a$ and $a \cdot_{m} 1 = a$.

  - **Additive inverses:** If $a \neq 0$ belongs to $\mathbb{Z}_m$, then $m - a$ is the additive inverse of $a$ modulo $m$, and 0 is its own additive inverse.
    - $a +_{m} (m - a) = 0$ and $0 +_{m} 0 = 0$.

  - **Distributivity:** If $a$, $b$, and $c$ belong to $\mathbb{Z}_m$, then
    - $a \cdot_{m} (b +_{m} c) = (a \cdot_{m} b) +_{m} (a \cdot_{m} c)$ and
    - $(a +_{m} b) \cdot_{m} c = (a \cdot_{m} c) +_{m} (b \cdot_{m} c)$.

- Exercises 42-44 ask for proofs of these properties.
- Multiplicative inverses have not been included since they do not always exist. For example, there is no multiplicative inverse of 2 modulo 6.

---

**Example**

- What is the distributive property of multiplication over addition for $\mathbb{Z}_m$ with $m \geq 2$ an integer?

```
• Proof:
  by def and corollary 2
  Left side is $a(b+c)$ mod $m$
  Right side is $ab + bc$ mod $m$
  Thus $a(b+c)$ mod $m = ab + bc$ mod $m$
  Since mult. distributive over add. for integers
```

---

**Chap. 4.2 Representations of Integers**

- In the modern world, we use *decimal*, or *base* 10, *notation* to represent integers. For example when we write 965, we mean $9 \cdot 10^2 + 6 \cdot 10^1 + 5 \cdot 10^0$.

- We can represent numbers using any base $b$, where $b$ is a positive integer greater than 1.

- The bases $b = 2$ (*binary*), $b = 8$ (*octal*), and $b = 16$ (*hexadecimal*) are important for computing and communications.

- The ancient Mayans used base 20 and the ancient Babylonians used base 60.
Base $b$ Representations

- We can use positive integer $b$ greater than 1 as a base, because of this theorem:

  **Theorem 1**: Let $b$ be a positive integer greater than 1. Then if $n$ is a positive integer, it can be expressed uniquely in the form:

  $$n = a_k b^k + a_{k-1} b^{k-1} + \ldots + a_1 b + a_0$$

  where $k$ is a nonnegative integer, $a_0, a_1, \ldots, a_k$ are nonnegative integers less than $b$, and $a_k \neq 0$. The $a_j, j = 0, \ldots, k$ are called the base-$b$ digits of the representation.

- The representation of $n$ given in Theorem 1 is called the base-$b$ expansion of $n$ and is denoted by $(a_ka_{k-1}\ldots a_0)_b$.
- We usually omit the subscript 10 for base 10 expansions.

Binary Expansions

Most computers represent integers and do arithmetic with binary (base 2) expansions of integers. In these expansions, the only digits used are 0 and 1.

**Example**: What is the decimal expansion of the integer that has $(101001011)_2$ as its binary expansion?

**Solution**: 

**Example**: What is the decimal expansion of the integer that has $(11001)_2$ as its binary expansion?

**Solution**:

Octal Expansions

The octal expansion (base 8) uses the digits \{0,1,2,3,4,5,6,7\}.

**Example**: What is the decimal expansion of the number with octal expansion $(4016)_8$?

**Example**: What is the decimal expansion of the number with octal expansion $(111)_8$?

**Example**: What is the decimal expansion of the number with hexadecimal expansion $(2AE0B)_{16}$?

**Example**: What is the decimal expansion of the number with hexadecimal expansion $(E5)_{16}$?

Hexadecimal Expansions

The hexadecimal expansion needs 16 digits, but our decimal system provides only 10. So letters are used for the additional symbols. The hexadecimal system uses the digits \{0,1,2,3,4,5,6,7,8,9,A,B,C,D,E,F\}. The letters A through F represent the decimal numbers 10 through 15.

**Example**: What is the decimal expansion of the number with hexadecimal expansion $(2AE0B)_{16}$?

**Example**: What is the decimal expansion of the number with hexadecimal expansion $(E5)_{16}$?
Base Conversion

To construct the base $b$ expansion of an integer $n$:

- Divide $n$ by $b$ to obtain a quotient and remainder.
  
  \[ n = bq_0 + a_0 \quad 0 \leq a_0 \leq b \]
- The remainder, $a_0$, is the rightmost digit in the base $b$ expansion of $n$. Next, divide $q_0$ by $b$.
  
  \[ q_0 = bq_1 + a_1 \quad 0 \leq a_1 \leq b \]
- The remainder, $a_1$, is the second digit from the right in the base $b$ expansion of $n$.
- Continue by successively dividing the quotients by $b$, obtaining the additional base $b$ digits as the remainder. The process terminates when the quotient is 0.

\[ continued \rightarrow 40 \]

Algorithm: Constructing Base $b$ Expansions

\[
\text{procedure } base\ b\ expansion(n, b: \text{positive integers with } b > 1) \\
q := n \\
k := 0 \\
\text{while } (q \neq 0) \\
a_k := q \mod b \\
q := q \div b \\
k := k + 1 \\
\text{return}(a_{k-1}, \ldots, a_1, a_0) \{(a_{k-1} \ldots a_1a_0)_b \text{ is base } b \text{ expansion of } n\} \\
\]

- $q$ represents the quotient obtained by successive divisions by $b$, starting with $q = n$.
- The digits in the base $b$ expansion are the remainders of the division given by $q \mod b$.
- The algorithm terminates when $q = 0$ is reached.

Comparison of Hexadecimal, Octal, and Binary Representations

Initial 0s are not shown

Each octal digit corresponds to a block of 3 binary digits.
Each hexadecimal digit corresponds to a block of 4 binary digits.
So, conversion between binary, octal, and hexadecimal is easy.
Conversion Between Binary, Octal, and Hexadecimal Expansions

Example: Find the octal and hexadecimal expansions of \((111110111100)_2\).

Solution:

To convert to octal, we group the digits into blocks of three (\((111110111100)\)’), adding initial \(\cdot\)s as needed. The blocks from left to right correspond to the digits \(3\), \(3\), \(4\), \(3\), and \(6\). Hence, the solution is \((33436)\)_8.

To convert to hexadecimal, we group the digits into blocks of four (\((111110111100)\)’), adding initial \(\cdot\)s as needed. The blocks from left to right correspond to the digits \(3\), \(3\), \(4\), \(3\), and \(6\). Hence, the solution is \((33436)\)_16.

Binary Addition of Integers

- Algorithms for performing operations with integers using their binary expansions are important as computer chips work with binary numbers. Each digit is called a bit.

**procedure** add\((a, b: \text{positive integers})\)

\{the binary expansions of \(a\) and \(b\) are \((a_{n-1}, a_{n-2}, \ldots, a_0)_2\) and \((b_{n-1}, b_{n-2}, \ldots, b_0)_2\), respectively\}

\(c := 0\)

for \(j := 0\) to \(n - 1\)

if \(b_j = 1\) then \(c_j := a\) shifted \(j\) places
else \(c_j := 0\)

\(\{c_0, c_1, \ldots, c_{n-1}\} \text{ are the partial products}\)

\(p := 0\)

for \(j := 0\) to \(n - 1\)

\(p := p + c_j\)

return \(p\) \{\(p\) is the value of \(ab\)\}

- The number of additions of bits used by the algorithm to add two \(n\)-bit integers is \(O(n)\).

Binary Multiplication of Integers

- Algorithm for computing the product of two \(n\) bit integers.

**procedure** multiply\((a, b: \text{positive integers})\)

\{the binary expansions of \(a\) and \(b\) are \((a_{n-1}, a_{n-2}, \ldots, a_0)_2\) and \((b_{n-1}, b_{n-2}, \ldots, b_0)_2\), respectively\}

for \(j := 0\) to \(n - 1\)

if \(b_j = 1\) then \(c_j := a\) shifted \(j\) places
else \(c_j := 0\)

\(\{c_0, c_1, \ldots, c_{n-1}\} \text{ are the partial products}\)

\(p := 0\)

for \(j := 0\) to \(n - 1\)

\(p := p + c_j\)

return \(p\) \{\(p\) is the value of \(ab\)\}

- The number of additions of bits used by the algorithm to multiply two \(n\)-bit integers is \(O(n^2)\).  

Binary Modular Exponentiation

- In cryptography, it is important to be able to find \(b^n \mod m\) efficiently, where \(b, n,\) and \(m\) are large integers.

- Use the binary expansion of \(n, n = (a_k, \ldots, a_1, a_0)_2\), to compute \(b^n\).

  Note that:

  \(b^n = b^{a_k \cdot 2^{k-1}} \cdot \ldots \cdot b^{a_1 \cdot 2} \cdot b^{a_0}\)

  Therefore, to compute \(b^n\), we need only compute the values of \(b, b^2, (b^2)^2 = b^4, (b^4)^2 = b^8, \ldots, b^{2^i}\) and the multiply the terms \(b^{2^i}\) in this list, where \(a_j = 1\).

**Example:** Compute \(3^{11}\) using this method.

continued \(\rightarrow 49\)
