**Announcements (October 27)**

- Homework #3 due next Tuesday
- Project milestone #2 due Nov. 10

---

**SAX & DOM**

- Both are API’s for XML processing
- SAX (Simple API for XML)
  - Started out as a Java API, but now exists for other languages too
- DOM (Document Object Model)
  - Language-neutral API with implementations in Java, C++, etc.
- JAXP (Java API for XML Processing)
  - Bundled with standard JDK
  - Includes SAX, DOM parsers and XSLT transformers

---

**SAX processing model**

- Serial access
  - XML document is processed as a stream
  - Only one look at the data
  - Cannot go back to an early portion of the document
- Event-driven
  - A parser generates events as it goes through the document (e.g., start of the document, end of an element, etc.)
  - Application defines event handlers that get invoked when events are generated

---

**SAX events**

- Most frequently used events:
  - `startDocument`
  - `endDocument`
  - `startElement`
  - `endElement`
  - `characters`

  * Whenever the parser has processed a chunk of character data (without generating other kinds of events)
  * Warning: The parser may generate multiple `characters` events for one piece of text

---

**A simple SAX example**

- Print out text contents of `title` elements

```java
import java.io.*;
import org.xml.sax.*;
import org.xml.sax.helpers.DefaultHandler;
import javax.xml.parsers.*;

public class SaxExample extends DefaultHandler {
    public static void main(String[] argv) throws Exception {
        String fileName = argv[0];
        // Create a SAX parser:
        SAXParserFactory factory = SAXParserFactory.newInstance();
        SAXParser saxParser = factory.newSAXParser();
        // Parse the document with this event handler:
        DefaultHandler handler = new SaxExample();
        saxParser.parse(new File(fileName), handler);
    }
}
```
A simple SAX example (cont’d)

```java
private StringBuffer titleStringBuffer = null;
public void startElement(String uri, String localName, String qName, Attributes attributes) {
    if (qName.equals("title"))
        titleStringBuffer = new StringBuffer();
}
public void endElement(String uri, String localName, String qName) {
    if (qName.equals("title")) {
        System.out.println(titleStringBuffer.toString());
        titleStringBuffer = null;
    }
}
public void characters(char[] ch, int start, int length) {
    if (titleStringBuffer != null)
        titleStringBuffer.append(ch, start, length);
}
```

Warning: This code does not handle data with 
//title[/title] pattern

A more complex SAX example (cont’d)

```java
private ArrayList path = new ArrayList();
private int pathLengthWhenOutputIsActivated;
```

A more complex SAX example (cont’d)

```java
public void startElement(String uri, String localName, String qName, Attributes attributes) {
    path.add(qName); // Maintain the path.
    if (path.size() >= 3 && ((String)(path.get(path.size()-1))).equals("title") &&
        ((String)(path.get(path.size()-2))).equals("section") &&
        ((String)(path.get(path.size()-3))).equals("book") ) {
        // path matches //book/section/title:
        if (titleStringBuffer == null) {
            pathLengthWhenOutputIsActivated = path.size();
            titleStringBuffer = new StringBuffer();
        }
    }
}
```

This check prevents premature output in case that title has subelements

A more complex SAX example (cont’d)

```java
public void endElement(String uri, String localName, String qName) {
    if (titleStringBuffer != null && path.size() == pathLengthWhenOutputIsActivated) {
        // Closing the element that activated output buffering:
        System.out.println(titleStringBuffer.toString());
        titleStringBuffer = null;
    }
    path.remove(path.size()-1); // Maintain the path.
}
```

This check prevents premature output in case that title has subelements

A common mistake

What is wrong with the following?
```
private String titleString = null;
public void endElement(String uri, String localName, String qName) {
    // Print the last chunk of characters seen before </title>:
    if (qName.equals("title"))
        System.out.println(titleString);
}
public void characters(char[] ch, int start, int length) {
    titleString = new String(ch, start, length);
}
```

- Cannot handle the case where other tags appear within a title element
- It is possible that characters() are called multiple times for one piece of text; this code only prints out the last part

A more complex SAX example

- Print out the text contents of top-level section titles in books, i.e., //book//section//title
  - Old code would print out all titles, e.g., //book//title, //book//section//title
  - For simplicity, assume that if we have the pattern //book//section//title//book//section//title, we print the higher-level title element
- Idea: maintain as state the path from the root

```
private ArrayList path = new ArrayList();
private int pathLengthWhenOutputIsActivated;
```

DOM processing model

- XML is parsed by a parser and converted into an in-memory DOM tree
- DOM API allows an application to
  - Construct a DOM tree from an XML document
  - Traverse and read a DOM tree
  - Construct a new, empty DOM tree from scratch
  - Modify an existing DOM tree
  - Copy subtrees from one DOM tree to another etc.
DOM Node’s

- A DOM tree is made up of Node’s
- Most frequently used types of Node’s:
  - Document: root of the DOM tree
  - DocumentType: corresponds to the DOCTYPE declaration in an XML document
  - Element: corresponds to an XML element
  - Attr: corresponds to an attribute of an XML element
  - Text: corresponds to chunk of text

DOM example

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml">
<head></head>
<body>
<h1>Hello, world!</h1>
</body>
</html>
```

Node interface

- `n.getNodeType()`: returns the type of Node n
- `n.getChildNodes()`: returns a NodeList containing Node n’s children
  - For example, subelements are children of an Element; DocumentType is a child of the Document
- `n.getTagName()`: returns the tag name of Element
- `n.getAttributes()`: returns a NamedNodeMap (hash table) containing the attributes of Element
  - Attributes are not considered children!
- `a.getName()` returns the name of Attr a
- `a.getValue()`: returns the value of Attr a
- `t.getValue()`: returns the content of Text t

For convenience: `n.getParentNode()`, `n.getPreviousSibling()`, `n.getNextSibling()`, `n.getOwnerDocument()`, etc.

Constructing DOM from XML

```java
import java.io.*;
import javax.xml.parsers.*;
import org.w3c.dom.*;
import javax.xml.transform.*;
import javax.xml.transform.dom.*;
import javax.xml.transform.stream.*;

public class DomExample {
    public static void main(String[] argv) throws Exception {
        // Parse input XML into a DOM Document:
        DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
        DocumentBuilder builder = factory.newDocumentBuilder();
        Document document = builder.parse(new File(argv[0]));

        // Use the default (identity) Transformer to print the DOM Document:
        TransformerFactory tFactory = TransformerFactory.newInstance();
        Transformer transformer = tFactory.newTransformer();
        transformer.transform(new DOMSource(document),
                              new StreamResult(System.out));
    }
}
```

Traversing DOM

- Compute the string value of an XML node

```java
public static String convertNodeToString(Node n) {
    // String value of a Text Node is just its content:
    if (n.getNodeType() == Node.TEXT_NODE)
        return n.getNodeValue();
    // String value of a Node of another type is the concatenation
    // of its children’s string values:
    String text = "";
    NodeList children = n.getChildNodes();
    for (int i=0; i<children.getLength(); i++) {
        Node child = children.item(i);
        text = text + convertNodeToString(child);
    }
    return text;
}
```

- Print out text contents of title elements

```java
public static void outputTitle(Node n) {
    if (n.getNodeType() == Node.ELEMENT_NODE &&
        n.getNodeName().equals("title")) {
        // This is a title Element; output it:
        System.out.println(convertNodeToString(n));
    } else {
        // Recurse down the tree and look for titles to output:
        NodeList children = n.getChildNodes();
        for (int i=0; i<children.getLength(); i++) {
            Node child = children.item(i);
            outputTitle(child);
        }
    }
}
```

- How would you print out just `//book/section/title`?
  - Use `getParentNode()` to check for `section` parent and `book` grandparent.
### Constructing DOM from scratch

- Construct a DOM Document showing all titles as follows:
  ```xml
  <result>
  <title text="title1"/>
  <title text="title2"/>
  </result>
  ```

```java
public static Document newDocWithTitles(Document inputDoc)
throws Exception {
  // Create a new Document:
  DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
  DocumentBuilder builder = factory.newDocumentBuilder();
  Document newDoc = builder.newDocument();
  // Create the root Element:
  Element newElement = newDoc.createElement("result");
  newDoc.appendChild(newElement);
  // Add titles:
  addTitlesToNewDoc(newDoc, inputDoc);
  return newDoc;
}
```

### Constructing DOM from scratch (cont’d)

```java
public static void addTitlesToNewDoc(Document newDoc, Node n)
throws Exception {
  if (n.getNodeType() == Node.ELEMENT_NODE
      && n.getNodeName().equals("title")) {
    // This is a title Element; add it:
    Element newElement = newDoc.createElement("title");
    newElement.setAttribute("text", convertNodeToString(n));
    newDoc.getDocumentElement().appendChild(newElement);
  } else {
    // Recurse down the tree and look for titles to add:
    NodeList children = n.getChildNodes();
    for (int i=0; i<children.getLength(); i++) {
      Node child = children.item(i);
      addTitlesToNewDoc(newDoc, child);
    }
  }
}
```

### Copying subtrees in DOM

- Construct a DOM Document showing all title elements from the input XML

```java
public static Document newDocWithTitles2(Document inputDoc)
throws Exception {
  // Add titles:
  addTitlesToNewDoc2(newDoc, inputDoc);
}
```

```java
public static void addTitlesToNewDoc2(Document newDoc, Node n)
throws Exception {
  if (n.getNodeType() == Node.ELEMENT_NODE
      && n.getNodeName().equals("title")) {
    Node newNode = newDoc.importNode(n, true);
    newDoc.getDocumentElement().appendChild(newNode);
  } else {
    // A Document can import (copy) a Node from another element
    // The second argument specifies whether to copy recursively or not
    }
}
```

### Summary: SAX versus DOM

- **SAX**
  - Because of one-pass processing, a SAX parser is fast, consumes very little memory, and scales to very large XML documents
  - Applications are responsible for keeping necessary state in memory, and are therefore more difficult to code

- **DOM**
  - Because the input XML needs to be converted to an in-memory DOM-tree representation, a DOM parser consumes more memory, and does not scale as well as a SAX parser
  - Applications are easier to develop because of the powerful DOM interface
