Announcements (October 19)

- Homework #3 assigned today
  - Due on October 31
- Project milestone #1 feedbacks available by the end of today, or tomorrow at the latest

XQuery

- XPath + full-fledged SQL-like query language
- XQuery expressions can be
  - XPath expressions
  - FLWOR (🇺🇸) expressions
  - Quantified expressions
  - Aggregation, sorting, and more…
- An XQuery expression in general can return a new result XML document
  - Compare with an XPath expression, which always returns a sequence of nodes from the input document or atomic values (boolean, number, string, etc.)
A simple XQuery based on XPath

Find all books with price lower than $50
<result>
  { doc("bib.xml")/bibliography/book[@price<50] }
</result>

- Things outside {}'s are copied to output verbatim
- Things inside {}'s are evaluated and replaced by the results
  - doc("bib.xml") specifies the document to query
    - Can be omitted if there is a default context document
  - The XPath expression returns a sequence of book elements
  - These elements (including all their descendants) are copied to output

FLWR expressions

- Retrieve the titles of books published before 2000, together with their publisher
  <result>
    for $b in doc("bib.xml")/bibliography/book
    where $b/year < 2000
    return <book>
      { $b/title }<book/>
    </book>
  </result>

- Invoked in the "innermost loop," i.e., once for each successful binding of all query variables that satisfies where

An equivalent formulation

- Retrieve the titles of books published before 2000, together with their publisher
  <result>
    for $b in doc("bib.xml")/bibliography/book[year<2000]
    return <book>
      { $b/title }
      { $b/publisher }
    </book>
  </result>

Another formulation

- Retrieve the titles of books published before 2000, together with their publisher

```xml
<result>
  for $b in doc("bib.xml")/bibliography/book,
  $p in $b/publisher
  where $b/year < 2000
  return
  <book>
    { $b/title }
    { $p }
  </book>
</result>
```

- Is this query equivalent to the previous two?

Yet another formulation

- Retrieve the titles of books published before 2000, together with their publisher

```xml
<result>
  let $b := doc("bib.xml")/bibliography/book
  where $b/year < 2000
  return
  <book>
    { $b/title }
    { $b/publisher }
  </book>
</result>
```

- Is this query correct?

Subqueries in return

- Extract book titles and their authors; make title an attribute and rename author to writer

```xml
<bibliography>
  for $b in doc("bib.xml")/bibliography/book
  cal $a in $b/author
  return
  <book title="{normalize-space($b/title)}"><{
    for $a in $b/author
    writer="{string($a)}"></writer>
  }/book>
</bibliography>
```

- `normalize-space(string)` removes leading and trailing spaces from string, and replaces all internal sequences of white spaces with one white space

- What happens if we replace it with `$a`?
An explicit join

- Find pairs of books that have common author(s)

```xml
<result>
  for $b1 in doc("bib.xml")//book
  for $b2 in doc("bib.xml")//book
  where $b1/author = $b2/author
  and $b1/title > $b2/title
  return
  <pair>
    {$b1/title}
  </pair>
</result>
```

These are string comparisons, not identity comparisons!

Existentially quantified expressions

(some $var in collection satisfies condition)

- Can be used in where as a condition

- Find titles of books in which XML is mentioned in some section

```xml
<result>
  for $b in doc("bib.xml")//book
  where (some $section in $b//section satisfies contains(string($section), "XML"))
  return $b/title
</result>
```

Universally quantified expressions

(every $var in collection satisfies condition)

- Can be used in where as a condition

- Find titles of books in which XML is mentioned in every section

```xml
<result>
  for $b in doc("bib.xml")//book
  where (every $section in $b//section satisfies contains(string($section), "XML"))
  return $b/title
</result>
```
Aggregation

- List each publisher and the average prices of all its books

```
<result>
    for $pub in distinct-values(doc("bib.xml")//publisher)
    let $price :=
        avg(doc("bib.xml")//book[publisher=$pub]/@price)
    return
        <publisherpricing>
            <publisher>{$pub}</publisher>
            <avgprice>{$price}</avgprice>
        </publisherpricing>
</result>
```

- `distinct-values(collation)` removes duplicates by value
  - If the collection consists of elements (with no explicitly declared types), they are first converted to strings representing their 'normalized contents'
  - `avg(collation)` computes the average of `collation` (assuming each item in `collation` can be converted to a numeric value)

Sorting (a brief history)

- XPath always returns a sequence of nodes in original document order
- `for` loop will respect the ordering in the sequence
- August 2002 (http://www.w3.org/TR/2002/WD-xquery-20020816/)
  - Introduce an operator `sort by` `(sort-by-expression-list)` to output results in a user-specified order
  - Example: list all books with price higher than $100, in order by first author, for books with the same first author, order by title

```
<result>
    doc("bib.xml")//book[@price>100]
    sort by (author[1], title)
</result>
```

Tricky semantics

- List titles of all books, sorted by their prices

```
<result>
    doc("bib.xml")//book sort by (@price))/title
</result>
```

- What is wrong?
  - A path expression always returns a sequence of nodes in document order.
- Correct versions
Current version of sorting

As of June 2006
- sort by has been ditched
- Add a new order by clause in FLWR (which now becomes FLWOR)
- Example: list all books with price higher than $100, in order by first author; for books with the same first author, order by title
  <result>{
    for $b in doc("bib.xml")//book[@price>100]
    stable order by $b/author[1], $b/title empty least
    return $b
  }</result>

Summary

- Many, many more features not covered in class
- XPath is fairly mature and stable
  - 1.0 is already a W3C recommendation
  - Implemented in many systems
  - Used in many other standards
  - 2.0 is being developed jointly with XQuery
- XQuery is still evolving
  - Still a W3C "candidate" recommendation
  - Many vendors are coming out with implementations
  - Poised to become the SQL for XML

XQuery vs. SQL

- Where did the join go?
- Is navigational query going to destroy physical data independence?
- Strong ordering constraint
  - Can be overridden by unordered { for... }
  - Why does that matter?
