Physical Data Organization

CPS 116
Introduction to Database Systems

Announcements (November 2)

• Deadline for Problem X1 of Homework #3 is today
• Project milestone #2 due in one week
  • You should be working with “production” dataset now

Outline

• It’s all about disks!
  • That’s why we always draw databases as
  • And why the single most important metric in database processing is the number of disk I/O’s performed
• Storing data on a disk
  • Record layout
  • Block layout
Storage hierarchy

- Registers
- Cache
- Memory
- Disk
- Tapes

Why a hierarchy?

How far away is data?

<table>
<thead>
<tr>
<th>Location</th>
<th>Cycles</th>
<th>Location</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registers</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>On-chip cache</td>
<td>2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>On-board cache</td>
<td>10</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Memory</td>
<td>100</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Disk</td>
<td>$10^6$</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Tape</td>
<td>$10^9$</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

I/O dominates—design your algorithms to reduce I/O!

A typical disk

- Tracks
- Platter
- Cylinders
- Disk arm
- Arm movement
- Spindle rotation

“Moving parts” are slow
Top view
Higher-density sectors on inner tracks
and/or more sectors on outer tracks

A block is a logical unit of transfer consisting of one or more sectors

Disk access time

Sum of:
- Seek time: time for disk heads to move to the correct cylinder
- Rotational delay: time for the desired block to rotate under the disk head
- Transfer time: time to read/write data in the block (= time for disk to rotate over the block)

Random disk access

Seek time + rotational delay + transfer time
- Average seek time
  - Time to skip one half of the cylinders?
  - “Typical” value: 5 ms
- Average rotational delay
  - Time for a half rotation (a function of RPM)
  - “Typical” value: 4.2 ms (7200 RPM)
Sequential disk access

Seek time + rotational delay + transfer time

- Seek time
  - 0 (assuming data is on the same track)
- Rotational delay
  - 0 (assuming data is in the next block on the track)
- Easily an order of magnitude faster than random disk access!

Performance tricks

- Disk layout strategy
  - Keep related things (what are they?) close together: same sector/block → same track → same cylinder → adjacent cylinder
- Double buffering
  - While processing the current block in memory, prefetch the next block from disk (overlap I/O with processing)
- Disk scheduling algorithm
  - Example: "elevator" algorithm
- Track buffer
  - Read/write one entire track at a time
- Parallel I/O
  - More disk heads working at the same time

Record layout

Record = row in a table

- Variable-format records
  - Rare in DBMS—table schema dictates the format
  - Relevant for semi-structured data such as XML
- Focus on fixed-format records
  - With fixed-length fields only, or
  - With possible variable-length fields
### Fixed-length fields

- All field lengths and offsets are constant
  - Computed from schema, stored in the system catalog
- Example: `CREATE TABLE Student(SID INT, name CHAR(20), age INT, GPA FLOAT);`

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>24</td>
<td>28</td>
<td>36</td>
<td></td>
</tr>
<tr>
<td>Bart (padded with space)</td>
<td>10</td>
<td>2.3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Watch out for alignment
  - May need to pad; reorder columns if that helps
- What about NULL?

### Variable-length records

- Example: `CREATE TABLE Student(SID INT, name VARCHAR(20), age INT, GPA FLOAT, comment VARCHAR(100));`
- Approach 1: use field delimiters ('\0' okay?)

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>16</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Bart\0</td>
<td>2.3</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Approach 2: use an offset array

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>8</td>
<td>16</td>
<td>18</td>
</tr>
<tr>
<td>Bart</td>
<td>2.3</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Put all variable-length fields at the end (why?)
- Update is messy if it changes the length of a field

### LOB fields

- Example: `CREATE TABLE Student(SID INT, name CHAR(20), age INT, GPA FLOAT, picture BLOB(32000));`
- Student records get "de-clustered"
  - Bad because most queries do not involve picture
- Decomposition (automatically done by DBMS and transparent to the user)
  - `Student(SID, name, age, GPA)`
  - `StudentPicture(SID, picture)`
Block layout

How do you organize records in a block?

- NSM (N-ary Storage Model)
  - Most commercial DBMS
- PAX (Partition Attributes Across)
  - Ailamaki et al., VLDB 2001

NSM

- Store records from the beginning of each block
- Use a directory at the end of each block
  - To locate records and manage free space
  - Necessary for variable-length records

Options

- Reorganize after every update/delete to avoid fragmentation (gaps between records)
  - Need to rewrite half of the block on average
- What if records are fixed-length?
Cache behavior of NSM

- Query: `SELECT SID FROM Student WHERE GPA > 2.0;`
- Assumption: cache block size < record size
- Lots of cache misses
  - ID and GPA are not close enough by memory standards

```
ID   GPA
---   ----
142   2.3
123   3.1
456   2.3
857   4.3
```

PAX

- Most queries only access a few columns
- Cluster values of the same columns in each block
  - When a particular column of a row is brought into the cache, the same column of the next row is brought in together
  - Reorganize after every update (for variable-length records only)
  - and delete to keep fields together

```
Bart    2.3
Milhouse 3.1
Ralph   2.3
Lisa    4.3
```

Summary

- Storage hierarchy
  - Why I/O's dominate the cost of database operations
- Disk
  - Steps in completing a disk access
  - Sequential versus random accesses
- Record layout
  - Handling variable-length fields
  - Handling NULL
  - Handling modifications
- Block layout
  - NSM: the traditional layout
  - PAX: a layout that tries to improve cache performance
