# Relational Database Design Theory

Introduction to Databases CompSci 316 Fall 2019

#### Announcements (Mon. Sep. 9)

- Gradiance ER due this Wednesday
- Gradiance FD and MVD assigned
- Homework 1 due next Monday (11:59pm)
  - RA debugger for Problem 1 available at https://ratest.cs.duke.edu/
- Course project description posted
  - Read it!
  - "Mixer" in a week and a half
  - Milestone 1 right after fall break
  - Teamwork required: 5 people per team on average

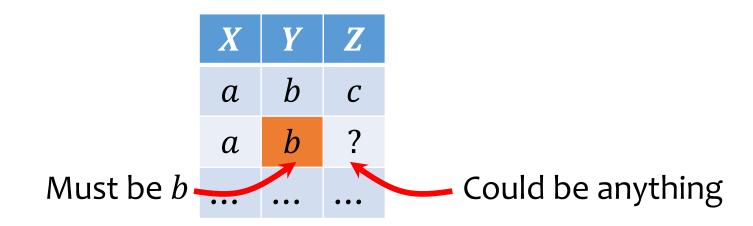

#### Motivation

uid	uname	gid
142	Bart	dps
123	Milhouse	gov
857	Lisa	abc
857	Lisa	gov
456	Ralph	abc
456	Ralph	gov
•••	•••	•••

- Why is UserGroup (<u>uid</u>, uname, <u>gid</u>) a bad design?
  - It has redundancy—user name is recorded multiple times, once for each group that a user belongs to
    - Leads to update, insertion, deletion anomalies
- Wouldn't it be nice to have a systematic approach to detecting and removing redundancy in designs?
  - Dependencies, decompositions, and normal forms

#### Functional dependencies

- A functional dependency (FD) has the form  $X \to Y$ , where X and Y are sets of attributes in a relation R
- $X \rightarrow Y$  means that whenever two tuples in R agree on all the attributes in X, they must also agree on all attributes in Y

#### FD examples

Address (street\_address, city, state, zip)

- street\_address, city, state → zip
- $zip \rightarrow city$ , state
- zip, state  $\rightarrow$  zip?
  - This is a trivial FD
  - Trivial FD: LHS ⊇ RHS
- $zip \rightarrow state, zip$ ?
  - This is non-trivial, but not completely non-trivial
  - Completely non-trivial FD: LHS  $\cap$  RHS =  $\emptyset$

# Redefining "keys" using FD's

A set of attributes *K* is a key for a relation *R* if

- $K \rightarrow \text{all (other)}$  attributes of R
  - That is, K is a "super key"
- No proper subset of K satisfies the above condition
  - That is, *K* is minimal

# Reasoning with FD's

#### Given a relation R and a set of FD's $\mathcal{F}$

- Does another FD follow from  $\mathcal{F}$ ?
  - Are some of the FD's in  $\mathcal{F}$  redundant (i.e., they follow from the others)?
- Is *K* a key of *R*?
  - What are all the keys of *R*?

#### Attribute closure

- Given R, a set of FD's  $\mathcal{F}$  that hold in R, and a set of attributes Z in R:
  - The closure of Z (denoted  $Z^+$ ) with respect to  $\mathcal{F}$  is the set of all attributes  $\{A_1, A_2, ...\}$  functionally determined by Z (that is,  $Z \to A_1 A_2$  ...)
- Algorithm for computing the closure
  - Start with closure = Z
  - If  $X \to Y$  is in  $\mathcal{F}$  and X is already in the closure, then also add Y to the closure
  - Repeat until no new attributes can be added

#### A more complex example

UserJoinsGroup (uid, uname, twitterid, gid, fromDate)
Assume that there is a 1-1 correspondence between
our users and Twitter accounts

- uid → uname, twitterid
- twitterid → uid
- uid, gid  $\rightarrow$  from Date

Not a good design, and we will see why shortly

#### Example of computing closure

- {gid, twitterid}<sup>+</sup> = ?
- twitterid → uid
  - Add uid
  - Closure grows to { gid, twitterid, uid }
- $uid \rightarrow uname$ , twitterid
  - Add uname, twitterid
  - Closure grows to { gid, twitterid, uid, uname }
- uid, gid  $\rightarrow$  from Date
  - Add fromDate
  - Closure is now all attributes in UserJoinsGroup

#### $\mathcal{F}$ includes: $uid \rightarrow uname$ , twitterid $twitterid \rightarrow uid$ uid, $gid \rightarrow fromDate$

# Using attribute closure

#### Given a relation R and set of FD's $\mathcal{F}$

- Does another FD  $X \to Y$  follow from  $\mathcal{F}$ ?
  - Compute  $X^+$  with respect to  $\mathcal{F}$
  - If  $Y \subseteq X^+$ , then  $X \to Y$  follows from  $\mathcal{F}$
- Is *K* a key of *R*?
  - Compute  $K^+$  with respect to  $\mathcal{F}$
  - If  $K^+$  contains all the attributes of R, K is a super key
  - Still need to verify that K is minimal (how?)

#### Rules of FD's

- Armstrong's axioms
  - Reflexivity: If  $Y \subseteq X$ , then  $X \to Y$
  - Augmentation: If  $X \to Y$ , then  $XZ \to YZ$  for any Z
  - Transitivity: If  $X \to Y$  and  $Y \to Z$ , then  $X \to Z$
- Rules derived from axioms
  - Splitting: If  $X \to YZ$ , then  $X \to Y$  and  $X \to Z$
  - Combining: If  $X \to Y$  and  $X \to Z$ , then  $X \to YZ$
- Using these rules, you can prove or disprove an FD given a set of FDs

#### Non-key FD's

- Consider a non-trivial FD X → Y where X is not a super key
  - Since X is not a super key, there are some attributes (say Z) that are not functionally determined by X

X	Y	Z
a	b	$c_1$
a	b	$c_2$
•••	•••	•••

That a should be mapped to b is recorded multiple times: redundancy, update/insertion/deletion anomaly

### Example of redundancy

UserJoinsGroup (uid, uname, twitterid, gid, fromDate)

• uid  $\rightarrow$  uname, twitterid

(... plus other FD's)

uid	uname	twitterid	gid	fromDate
142	Bart	@BartJSimpson	dps	1987-04-19
123	Milhouse	@MilhouseVan_	gov	1989-12-17
857	Lisa	@lisasimpson	abc	1987-04-19
857	Lisa	@lisasimpson	gov	1988-09-01
456	Ralph	@ralphwiggum	abc	1991-04-25
456	Ralph	@ralphwiggum	gov	1992-09-01
	•••		•••	

#### Decomposition

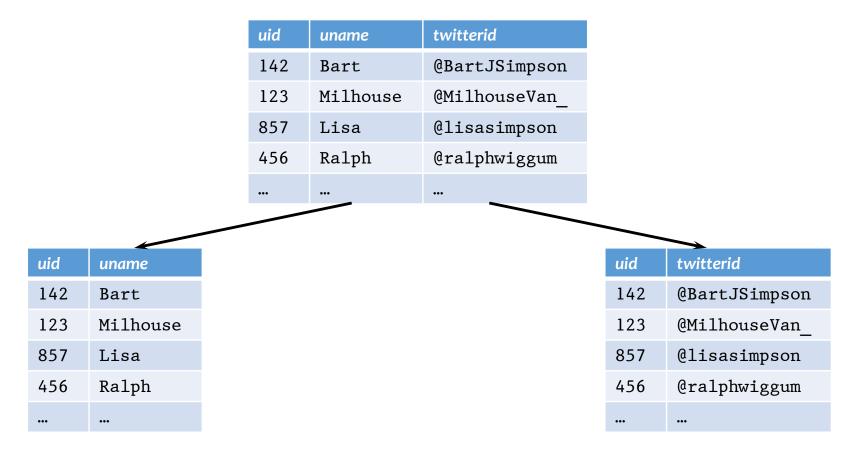

uid	uname	twitterid	gid	fromDate
142	Bart	@BartJSimpson	dps	1987-04-19
123	Milhouse	@MilhouseVan_	gov	1989-12-17
857	Lisa	@lisasimpson	abc	1987-04-19
857	Lisa	@lisasimpson	gov	1988-09-01
456	Ralph	@ralphwiggum	abc	1991-04-25
456	Ralph	@ralphwiggum	gov	1992-09-01
	•••		•••	

uid	uname	twitterid
142	Bart	@BartJSimpson
123	Milhouse	@MilhouseVan_
857	Lisa	@lisasimpson
456	Ralph	@ralphwiggum
•••	•••	•••

uid	gid	fromDate
142	dps	1987-04-19
123	gov	1989-12-17
857	abc	1987-04-19
857	gov	1988-09-01
456	abc	1991-04-25
456	gov	1992-09-01
•••	•••	•••

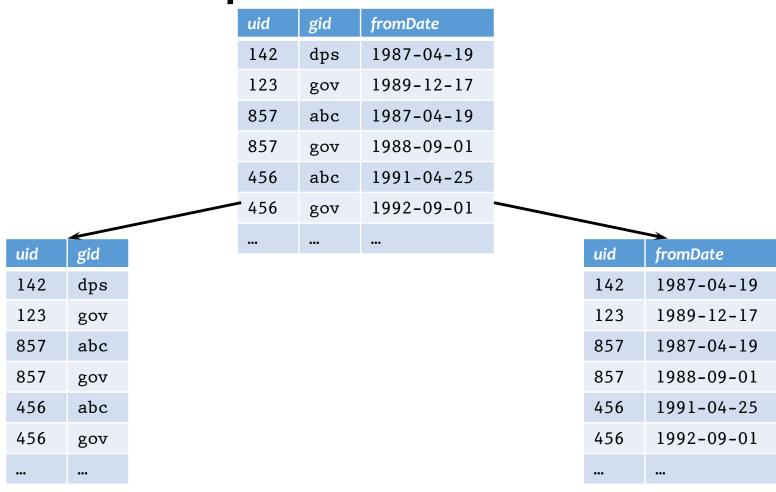

- Eliminates redundancy
- To get back to the original relation: ⋈

#### Unnecessary decomposition

- Fine: join returns the original relation
- Unnecessary: no redundancy is removed; schema is more complicated (and *uid* is stored twice!)

#### Bad decomposition

- Association between gid and fromDate is lost
- Join returns more rows than the original relation

#### Lossless join decomposition

- Decompose relation R into relations S and T
  - $attrs(R) = attrs(S) \cup attrs(T)$
  - $S = \pi_{attrs(S)}(R)$
  - $T = \pi_{attrs(T)}(R)$
- The decomposition is a lossless join decomposition if, given known constraints such as FD's, we can guarantee that  $R = S \bowtie T$
- Any decomposition gives  $R \subseteq S \bowtie T$  (why?)
  - A lossy decomposition is one with  $R \subset S \bowtie T$

# Loss? But I got more rows!

- "Loss" refers not to the loss of tuples, but to the loss of information
  - Or, the ability to distinguish different original relations

uid	gid	fromDate
142	dps	1987-04-19
123	gov	1989-12-17
857	abc	1988-09-01
857	gov	1987-04-19
456	abc	1991-04-25
456	gov	1992-09-01
•••	•••	

No way to tell which is the original relation

uid	fromDate
142	1987-04-19
123	1989-12-17
857	1987-04-19
857	1988-09-01
456	1991-04-25
456	1992-09-01

#### Questions about decomposition

When to decompose

 How to come up with a correct decomposition (i.e., lossless join decomposition)

#### An answer: BCNF

- A relation R is in Boyce-Codd Normal Form if
  - For every non-trivial FD  $X \to Y$  in R, X is a super key
  - That is, all FDs follow from "key → other attributes"
- When to decompose
  - As long as some relation is not in BCNF
- How to come up with a correct decomposition
  - Always decompose on a BCNF violation (details next)
  - Then it is guaranteed to be a lossless join decomposition!

# BCNF decomposition algorithm

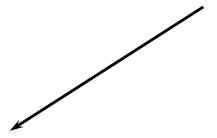

- Find a BCNF violation
  - That is, a non-trivial FD X → Y in R where X is not a super key of R
- Decompose R into  $R_1$  and  $R_2$ , where
  - $R_1$  has attributes  $X \cup Y$
  - $R_2$  has attributes  $X \cup Z$ , where Z contains all attributes of R that are in neither X nor Y
- Repeat until all relations are in BCNF

#### BCNF decomposition example

uid  $\rightarrow$  uname, twitterid twitterid  $\rightarrow$  uid uid, gid  $\rightarrow$  fromDate

UserJoinsGroup (uid, uname, twitterid, gid, fromDate)

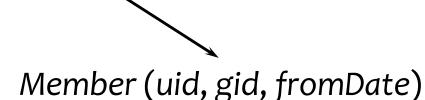

BCNF violation: uid  $\rightarrow$  uname, twitterid

User (uid, uname, twitterid)

uid  $\rightarrow$  uname, twitterid twitterid  $\rightarrow$  uid

**BCNF** 

uid, gid  $\rightarrow$  from Date

BCNF

#### Another example

uid  $\rightarrow$  uname, twitterid twitterid  $\rightarrow$  uid uid, gid  $\rightarrow$  fromDate

UserJoinsGroup (uid, uname, twitterid, gid, fromDate)

BCNF violation: twitterid  $\rightarrow$  uid UserId (twitterid, uid) **BCNF** UserJoinsGroup' (twitterid, uname, gid, fromDate) twitterid  $\rightarrow$  uname twitterid, gid  $\rightarrow$  from Date BCNF violation: twitterid → uname UserName (twitterid, uname) Member (twitterid, gid, fromDate) **BCNF** BCNF

#### Why is BCNF decomposition lossless

Given non-trivial  $X \to Y$  in R where X is not a super key of R, need to prove:

Anything we project always comes back in the join:

$$R \subseteq \pi_{XY}(R) \bowtie \pi_{XZ}(R)$$

- Sure; and it doesn't depend on the FD
- Anything that comes back in the join must be in the original relation:

$$R \supseteq \pi_{XY}(R) \bowtie \pi_{XZ}(R)$$

• Proof will make use of the fact that  $X \to Y$ 

#### Recap

- Functional dependencies: a generalization of the key concept
- Non-key functional dependencies: a source of redundancy
- BCNF decomposition: a method for removing redundancies
  - BNCF decomposition is a lossless join decomposition
- BCNF: schema in this normal form has no redundancy due to FD's

#### BCNF = no redundancy?

- User (uid, gid, place)
  - A user can belong to multiple groups
  - A user can register places she's visited
  - Groups and places have nothing to do with other
  - FD's?
    - None
  - BCNF?
    - Yes
  - Redundancies?
    - Tons!

uid	gid	place
142	dps	Springfield
142	dps	Australia
456	abc	Springfield
456	abc	Morocco
456	gov	Springfield
456	gov	Morocco
•••	•••	

#### Multivalued dependencies

- A multivalued dependency (MVD) has the form
   X → Y, where X and Y are sets of attributes in a
   relation R
- $X \rightarrow Y$  means that whenever two rows in R agree on all the attributes of X, then we can swap their Y components and get two rows that are also in R

X	Y	Z
a	$b_1$	$c_1$
a	$b_2$	$c_2$
a	$b_2$	$c_1$
a	$b_1$	$c_2$
• • •	•••	• • •

#### MVD examples

User (uid, gid, place)

- uid → gid
- uid → place
  - Intuition: given uid, gid and place are "independent"
- uid, gid → place
  - Trivial: LHS U RHS = all attributes of R
- uid, gid → uid
  - Trivial: LHS ⊇ RHS

#### Complete MVD + FD rules

- FD reflexivity, augmentation, and transitivity
- MVD complementation: If  $X \rightarrow Y$ , then  $X \rightarrow attrs(R) - X - Y$
- MVD augmentation: If  $X \rightarrow Y$  and  $V \subseteq W$ , then  $XW \rightarrow YV$
- MVD transitivity: If  $X \rightarrow Y$  and  $Y \rightarrow Z$ , then  $X \rightarrow Z Y$
- Replication (FD is MVD): If  $X \to Y$ , then  $X \to Y$  Try proving things using these!?
- Coalescence: If  $X \to Y$  and  $Z \subseteq Y$  and there is some W disjoint from Y such that  $W \to Z$ , then  $X \to Z$

### An elegant solution: chase

- Given a set of FD's and MVD's  $\mathcal{D}$ , does another dependency d (FD or MVD) follow from  $\mathcal{D}$ ?
- Procedure
  - Start with the premise of d, and treat them as "seed" tuples in a relation
  - Apply the given dependencies in  $\mathcal D$  repeatedly
    - If we apply an FD, we infer equality of two symbols
    - If we apply an MVD, we infer more tuples
  - If we infer the conclusion of d, we have a proof
  - Otherwise, if nothing more can be inferred, we have a counterexample

#### Proof by chase

• In R(A, B, C, D), does  $A \rightarrow B$  and  $B \rightarrow C$  imply that  $A \rightarrow C$ ?

Have: A B C D a  $b_1$   $c_1$   $d_1$ a  $b_2$   $c_2$   $d_2$  $A \Rightarrow B \quad \begin{array}{c|ccc} a & b_2 & c_1 & d_1 \\ \hline a & b_1 & c_2 & d_2 \end{array}$  $B \rightarrow C \quad \begin{array}{c|cccc} a & b_2 & c_1 & d_2 \\ \hline a & b_2 & c_2 & d_1 \end{array}$  $B \twoheadrightarrow C \quad \begin{array}{c|cccc} a & b_1 & c_2 & d_1 \\ \hline a & b_1 & c_1 & d_2 \end{array}$ 

#### Another proof by chase

• In R(A, B, C, D), does  $A \rightarrow B$  and  $B \rightarrow C$  imply that  $A \rightarrow C$ ?

Have:  $egin{array}{c|ccccc} A & B & C & D \\ \hline a & b_1 & c_1 & d_1 \\ \hline a & b_2 & c_2 & d_2 \\ \hline \end{array}$ 

Need:  $c_1 = c_2$ 

$$A \rightarrow B$$
  $b_1 = b_2$   $B \rightarrow C$   $c_1 = c_2$ 

In general, with both MVD's and FD's, chase can generate both new tuples and new equalities

#### Counterexample by chase

• In R(A, B, C, D), does  $A \rightarrow BC$  and  $CD \rightarrow B$  imply that  $A \rightarrow B$ ?

Have:  $egin{array}{c|cccc} A & B & C & D \\ \hline a & b_1 & c_1 & d_1 \\ \hline a & b_2 & c_2 & d_2 \\ \hline A \twoheadrightarrow BC & a & b_1 & c_1 & d_2 \\ \hline a & b_1 & c_1 & d_2 \\ \hline \end{array}$ 

Need:  $b_1 = b_2$  \$

Counterexample!

#### 4NF

- A relation R is in Fourth Normal Form (4NF) if
  - For every non-trivial MVD  $X \rightarrow Y$  in R, X is a superkey
  - That is, all FD's and MVD's follow from "key → other attributes" (i.e., no MVD's and no FD's besides key functional dependencies)
- 4NF is stronger than BCNF
  - Because every FD is also a MVD

### 4NF decomposition algorithm

- Find a 4NF violation
  - A non-trivial MVD  $X \rightarrow Y$  in R where X is not a superkey
- Decompose R into  $R_1$  and  $R_2$ , where
  - $R_1$  has attributes  $X \cup Y$
  - $R_2$  has attributes  $X \cup Z$  (where Z contains R attributes not in X or Y)
- Repeat until all relations are in 4NF
- Almost identical to BCNF decomposition algorithm
- Any decomposition on a 4NF violation is lossless

#### 4NF decomposition example

User (uid, gid, place)

4NF violation: uid → gid

#### Summary

- Philosophy behind BCNF, 4NF:
   Data should depend on the key,
   the whole key,
   and nothing but the key!
  - You could have multiple keys though
- Other normal forms
  - 3NF: More relaxed than BCNF; will not remove redundancy if doing so makes FDs harder to enforce
  - 2NF: Slightly more relaxed than 3NF
  - 1NF: All column values must be atomic
