SQL: Part I

Introduction to Databases

CompSci 316 Fall 2019

DUKE
COMPUTER SCIENCE

Announcements (Wed. Sep. 11)

- Gradiance ER due today, FD next Monday, and MVD next Wednesday
- Homework 1 due Monday 11:59pm
  - There is a FAQ for Homework 1 on Piazza
- Homework 2 assigned
- Project mixer next Wednesday in class
  - Please send me your slide(s) by next Monday if you want to make a pitch in front of the whole class!

SQL

- SQL: Structured Query Language
  - Pronounced “S-Q-L” or “sequel”
  - The standard query language supported by most DBMS
- A brief history
  - IBM System R
  - ANSI SQL89
  - ANSI SQL92 (SQL2)
  - ANSI SQL99 (SQL3)
  - ANSI SQL 2003 (added OLAP, XML, etc.)
  - ANSI SQL 2006 (added more XML)
  - ANSI SQL 2008, …

Creating and dropping tables

- `CREATE TABLE` *table_name* (…, *column_name column_type*, …);
- `DROP TABLE` *table_name*;
- Examples

```
create table User(uid integer, name varchar(30),
                  age integer, pop float);
create table Group(gid char(10), name varchar(100));
create table Member(uid integer, gid char(10));
drop table Member;
drop table Group;
drop table User;
-- everything from -- to the end of line is ignored.
-- SQL is insensitive to white space.
-- SQL is insensitive to case (e.g., ...Group... is
-- equivalent to ...GROUP...).
```

Basic queries: SFW statement

- SELECT $A_1, A_2, \ldots, A_n$
  FROM $R_1, R_2, \ldots, R_m$
  WHERE $condition;$
- Also called an SPJ (select-project-join) query
- Corresponds to (but not really equivalent to) relational algebra query:

$$\pi_{A_1,A_2,\ldots,A_n}\left(\sigma_{condition}(R_1 \times R_2 \times \cdots \times R_m)\right)$$

Example: reading a table

- `SELECT * FROM User;`
  - Single-table query, so no cross product here
  - `WHERE` clause is optional
  - `*` is a short hand for “all columns”

Example: selection and projection

- Name of users under 18
  - `SELECT name FROM User WHERE age<18;`
- When was Lisa born?
  - ```
    SELECT 2019-age
    FROM User
    WHERE name = 'Lisa';
    ```
  - `SELECT` list can contain expressions
    - Can also use built-in functions such as `SUBSTR`, `ABS`, etc.
  - String literals (case sensitive) are enclosed in single quotes
    ```

Example: join

- ID's and names of groups with a user whose name contains "Simpson"
  - ```
    SELECT Group.gid, Group.name
    FROM User, Member, Group
    WHERE User.uid = Member.uid
    AND Member.gid = Group.gid
    AND User.name LIKE '%Simpson%';
    ```
  - `LIKE` matches a string against a pattern
    - `%` matches any sequence of zero or more characters
  - Okay to omit *table_name* in *table_name*.*column_name* if *column_name* is unique
    ```

Example: rename

- ID's of all pairs of users that belong to one group
  - Relational algebra query:

    $\pi_{m_1.uid,m_2.uid}$
    $\left(\rho_{m_1} Member \bowtie_{m_1.gid=m_2.gid \wedge m_1.uid>m_2.uid} \rho_{m_2} Member\right)$
  - SQL:

```
SELECT m1.uid AS uid1, m2.uid AS uid2
FROM Member AS m1, Member AS m2
WHERE m1.gid = m2.gid
AND m1.uid > m2.uid;
```

  - AS keyword is completely optional

A more complicated example

- Names of all groups that Lisa and Ralph are both in

```
SELECT g.name
FROM User u1, User u2, Member m1, Member m2, Group g
WHERE u1.name = 'Lisa' AND u2.name = 'Ralph'
AND u1.uid = m1.uid AND u2.uid = m2.uid
AND m1.gid = g.gid AND m2.gid = g.gid;
```

Tip: Write the `FROM` clause first, then `WHERE`, and then `SELECT`

Why SFW statements?

- Out of many possible ways of structuring SQL statements, why did the designers choose `SELECT-FROM-WHERE`?
  - A large number of queries can be written using only selection, projection, and cross product (or join)
  - Any query that uses only these operators can be written in a canonical form: $\pi_L\left(\sigma_p(R_1\times\cdots\times R_m)\right)$
    - Example: $\pi_{R.A,S.B}\left(R \bowtie_{p_1} S\right) \bowtie_{p_2} \left(\pi_{T.C}\sigma_{p_3}T\right)$
      $= \pi_{R.A,S.B,T.C}\sigma_{p_1\wedge p_2\wedge p_3}(R\times S\times T)$
  - `SELECT-FROM-WHERE` captures this canonical form

Set versus bag semantics

- Set
  - No duplicates
  - Relational model and algebra use set semantics
- Bag
  - Duplicates allowed
  - Number of duplicates is significant
  - SQL uses bag semantics by default

Set versus bag example

Member

uid	*gid*
142	dps
123	gov
857	abc
857	gov
456	abc
456	gov
…	…

$\pi_{gid} Member$

gid
dps
gov
abc
…

```
SELECT gid
FROM Member;
```

gid
dps
gov
abc
gov
abc
gov
…

A case for bag semantics

- Efficiency
  - Saves time of eliminating duplicates
- Which one is more useful?
  - $\pi_{age} User$
  - `SELECT age FROM User;`
  - The first query just returns _____
  - The second query returns _____
- Besides, SQL provides the option of set semantics with `DISTINCT` keyword

Forcing set semantics

- ID's of all pairs of users that belong to one group
  - `SELECT m1.uid AS uid1, m2.uid AS uid2 FROM Member AS m1, Member AS m2 WHERE m1.gid = m2.gid AND m1.uid > m2.uid;`
    - Say Lisa and Ralph are in both the book club and the student government
  - `SELECT DISTINCT m1.uid AS uid1, m2.uid AS uid2 …`
    - With `DISTINCT`, all duplicate (`uid1`, `uid2`) pairs are removed from the output

Semantics of SFW

- `SELECT [DISTINCT]` E_1`,` E_2`, …,` E_n
  `FROM` R_1`,` R_2`, …,` R_m
  `WHERE` $condition$`;`
- For each t_1 in R_1:
  For each t_2 in R_2: … …
  For each t_m in R_m:
  If $condition$ is true over $t_1, t_2, \ldots, t_m$:
  Compute and output $E_1, E_2, \ldots, E_n$ as a row
  If `DISTINCT` is present
  Eliminate duplicate rows in output
- $t_1, t_2, \ldots, t_m$ are often called tuple variables

SQL set and bag operations

- `UNION`, `EXCEPT`, `INTERSECT`
  - Set semantics
    - Duplicates in input tables, if any, are first eliminated
    - Duplicates in result are also eliminated (for `UNION`)
  - Exactly like set ∪, −, and ∩ in relational algebra
- `UNION ALL`, `EXCEPT ALL`, `INTERSECT ALL`
  - Bag semantics
  - Think of each row as having an implicit count (the number of times it appears in the table)
  - Bag union: sum up the counts from two tables
  - Bag difference: proper-subtract the two counts
  - Bag intersection: take the minimum of the two counts

Examples of bag operations

Bag1

fruit
apple
apple
orange

Bag2

fruit
apple
orange
orange

```
(SELECT * FROM Bag1)
UNION ALL
(SELECT * FROM Bag2);
```

fruit
apple
apple
orange
apple
orange
orange

```
(SELECT * FROM Bag1)
EXCEPT ALL
(SELECT * FROM Bag2);
```

fruit
apple

```
(SELECT * FROM Bag1)
INTERSECT ALL
(SELECT * FROM Bag2);
```

fruit
apple
orange

Examples of set versus bag operations

Poke (*uid1*, *uid2*, *timestamp*)

- `(SELECT uid1 FROM Poke)`
  `EXCEPT`
  `(SELECT uid2 FROM Poke);`
  - Users who:
- `(SELECT uid1 FROM Poke)`
  `EXCEPT ALL`
  `(SELECT uid2 FROM Poke);`
  - Users who:

SQL features covered so far

- `SELECT-FROM-WHERE` statements (select-project-join queries)
- Set and bag operations

☞Next: how to nest SQL queries

Table subqueries

- Use query result as a table
  - In set and bag operations, `FROM` clauses, etc.
  - A way to "nest" queries
- Example: names of users who poked others more than others poked them
  - ```
    SELECT DISTINCT name
    FROM User,
         ((SELECT uid1 AS uid FROM Poke)
          EXCEPT ALL
          (SELECT uid2 AS uid FROM Poke))
        AS T
    WHERE User.uid = T.uid;
    ```
    ```

Scalar subqueries

- A query that returns a single row can be used as a value in `WHERE`, `SELECT`, etc.
- Example: users at the same age as Bart
  - ```
    SELECT *
    FROM User
    WHERE age = (SELECT age
                 FROM User
                 WHERE name = 'Bart');
    ```
    What's Bart's age?
  - Runtime error if subquery returns more than one row
    - Under what condition will this error never occur?
  - What if the subquery returns no rows?
    - The answer is treated as a special value `NULL`, and the comparison with `NULL` will fail
    ```

IN subqueries

- x `IN (`$subquery$`)` checks if x is in the result of $subquery$
- Example: users at the same age as (some) Bart
  - ```
    SELECT *
    FROM User
    WHERE age IN (SELECT age
                  FROM User
                  WHERE name = 'Bart');
    ```

What's Bart's age?
    ```

EXISTS subqueries

- `EXISTS (`*subquery*`)` checks if the result of *subquery* is non-empty
- Example: users at the same age as (some) Bart
  - ```
    SELECT *
    FROM User AS u
    WHERE EXISTS (SELECT * FROM User
                  WHERE name = 'Bart'
                  AND age = u.age);
    ```
  - This happens to be a correlated subquery—a subquery that references tuple variables in surrounding queries
    ```

Semantics of subqueries

- ```
  SELECT *
  FROM User AS u
  WHERE EXISTS (SELECT * FROM User
                WHERE name = 'Bart'
                AND age = u.age);
  ```

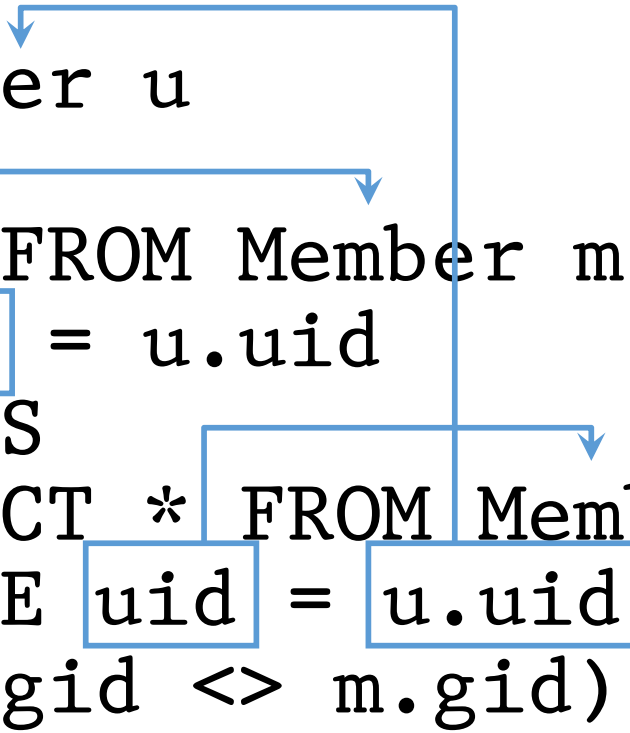
- For each row `u` in `User`
  - Evaluate the subquery with the value of `u.age`
  - If the result of the subquery is not empty, output `u.*`
- The DBMS query optimizer may choose to process the query in an equivalent, but more efficient way (example?)
  ```

Scoping rule of subqueries

- To find out which table a column belongs to
  - Start with the immediately surrounding query
  - If not found, look in the one surrounding that; repeat if necessary
- Use *table_name*.*column_name* notation and AS (renaming) to avoid confusion

Another example

- ```
  SELECT * FROM User u
  WHERE EXISTS
        (SELECT * FROM Member m
         WHERE uid = u.uid
         AND EXISTS
              (SELECT * FROM Member
               WHERE uid = u.uid
               AND gid <> m.gid));
  ```



- Users who:
  ```

Quantified subqueries

- A quantified subquery can be used syntactically as a value in a `WHERE` condition
- Universal quantification (for all):
  … `WHERE` x op `ALL` (*subquery*) …
  - True iff for all t in the result of *subquery*, $x\ op\ t$
- Existential quantification (exists):
  … `WHERE` x op `ANY` (*subquery*) …
  - True iff there exists some t in *subquery* result such that $x\ op\ t$

  ☞ Beware
  - In common parlance, “any” and “all” seem to be synonyms
  - In SQL, `ANY` really means “some”

Examples of quantified subqueries

- Which users are the most popular?
  - ```
    SELECT *
    FROM User
    WHERE pop >= ALL(SELECT pop FROM User);
    ```
  - ```
    SELECT *
    FROM User
    WHERE NOT
         (pop < ANY(SELECT pop FROM User);
    ```
  - ☞Use NOT to negate a condition

More ways to get the most popular

- Which users are the most popular?

  - ```
    SELECT *
    FROM User AS u
    WHERE NOT EXISTS
         (SELECT * FROM User
          WHERE pop > u.pop);
    ```

  - ```
    SELECT * FROM User
    WHERE uid NOT IN
         (SELECT u1.uid
          FROM User AS u1, User AS u2
          WHERE u1.pop < u2.pop);
    ```

SQL features covered so far

- `SELECT-FROM-WHERE` statements
- Set and bag operations
- Subqueries
  - Subqueries allow queries to be written in more declarative ways (recall the "most popular" query)
  - But in many cases they don't add expressive power
    - Try translating other forms of subqueries into `[NOT] EXISTS`, which in turn can be translated into join (and difference)
      - Watch out for number of duplicates though

☞Next: aggregation and grouping

Aggregates

- Standard SQL aggregate functions: `COUNT`, `SUM`, `AVG`, `MIN`, `MAX`
- Example: number of users under 18, and their average popularity
  - ```
    SELECT COUNT(*), AVG(pop)
    FROM User
    WHERE age < 18;
    ```
  - `COUNT(*)` counts the number of rows
    ```

Aggregates with DISTINCT

- Example: How many users are in some group?

  - ```
    SELECT COUNT(DISTINCT uid)
    FROM Member;
    ```

  is equivalent to:

  - ```
    SELECT COUNT(*)
    FROM (SELECT DISTINCT uid FROM Member);
    ```

Grouping

- `SELECT … FROM … WHERE …`
  `GROUP BY` *`list_of_columns`*`;`

- Example: compute average popularity for each age group
  - ```
    SELECT age, AVG(pop)
    FROM User
    GROUP BY age;
    ```
    ```

Semantics of GROUP BY

```
SELECT … FROM … WHERE … GROUP BY …;
```

- Compute FROM ($\times$)
- Compute WHERE (σ)
- Compute GROUP BY: group rows according to the values of GROUP BY columns
- Compute SELECT for each group (π)
  - For aggregation functions with DISTINCT inputs, first eliminate duplicates within the group

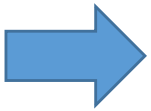
☞ Number of groups =
number of rows in the final output

Example of computing GROUP BY

```
SELECT age, AVG(pop) FROM User GROUP BY age;
```

uid	name	age	pop
142	Bart	10	0.9
857	Lisa	8	0.7
123	Milhouse	10	0.2
456	Ralph	8	0.3

Compute GROUP BY: group rows according to the values of GROUP BY columns



uid	name	age	pop
142	Bart	10	0.9
123	Milhouse	10	0.2
857	Lisa	8	0.7
456	Ralph	8	0.3

Compute SELECT for each group

age	avg_pop
10	0.55
8	0.50

Aggregates with no GROUP BY

- An aggregate query with no GROUP BY clause = all rows go into one group

```
SELECT AVG(pop) FROM User;
```

Group all rows into one group

Aggregate over the whole group

uid	name	age	pop
142	Bart	10	0.9
857	Lisa	8	0.7
123	Milhouse	10	0.2
456	Ralph	8	0.3

uid	name	age	pop
142	Bart	10	0.9
857	Lisa	8	0.7
123	Milhouse	10	0.2
456	Ralph	8	0.3

avg_pop
0.525

Restriction on SELECT

- If a query uses aggregation/group by, then every column referenced in SELECT must be either
  - Aggregated, or
  - A GROUP BY column

Why?

☞This restriction ensures that any SELECT expression produces only one value for each group

Examples of invalid queries

- WRONG!
  ```
  SELECT uid, age
  FROM User GROUP BY age;
  ```
  - Recall there is one output row per group
  - There can be multiple *uid* values per group
- WRONG!
  ```
  SELECT uid, MAX(pop) FROM User;
  ```
  - Recall there is only one group for an aggregate query with no GROUP BY clause
  - There can be multiple *uid* values
  - Wishful thinking (that the output *uid* value is the one associated with the highest popularity) does NOT work

  ☞Another way of writing the "most popular" query?

HAVING

- Used to filter groups based on the group properties (e.g., aggregate values, `GROUP BY` column values)
- `SELECT … FROM … WHERE … GROUP BY … HAVING` *condition*`;`
  - Compute `FROM` ($\times$)
  - Compute `WHERE` (σ)
  - Compute `GROUP BY`: group rows according to the values of `GROUP BY` columns
  - Compute `HAVING` (another σ over the groups)
  - Compute `SELECT` (π) for each group that passes `HAVING`

HAVING examples

- List the average popularity for each age group with more than a hundred users
  - ```
    SELECT age, AVG(pop)
    FROM User
    GROUP BY age
    HAVING COUNT(*) > 100;
    ```
  - Can be written using `WHERE` and table subqueries
- Find average popularity for each age group over 10
  - ```
    SELECT age, AVG(pop)
    FROM User
    GROUP BY age
    HAVING age > 10;
    ```
  - Can be written using `WHERE` without table subqueries

SQL features covered so far

- `SELECT-FROM-WHERE` statements
- Set and bag operations
- Subqueries
- Aggregation and grouping
  - More expressive power than relational algebra

☞Next: ordering output rows

ORDER BY

- `SELECT [DISTINCT] …`
  `FROM … WHERE … GROUP BY … HAVING …`
  `ORDER BY` *`output_column`* `[ASC|DESC], …;`
- `ASC` = ascending, `DESC` = descending
- Semantics: After `SELECT` list has been computed and optional duplicate elimination has been carried out, sort the output according to `ORDER BY` specification

ORDER BY example

- List all users, sort them by popularity (descending) and name (ascending)
  - ```
    SELECT uid, name, age, pop
    FROM User
    ORDER BY pop DESC, name;
    ```
  - ASC is the default option
  - Strictly speaking, only output columns can appear in ORDER BY clause (although some DBMS support more)
  - Can use sequence numbers instead of names to refer to output columns: `ORDER BY 4 DESC, 2;`
    ```

SQL features covered so far

- `SELECT-FROM-WHERE` statements
- Set and bag operations
- Subqueries
- Aggregation and grouping
- Ordering

☞ Next: `NULL`'s, outerjoins, data modification, constraints, …
