Transaction Processing

Introduction to Databases

CompSci 316 Fall 2019

Announcements (Mon., Dec. 2)

- Homework 4 due today
 - Except X2 (due Wed.)
- Project demos—sign-up instructions emailed
 - Early in-class demos this Wed. if you are up for up
 - Last weekly progress update due Wed. on Piazza
- Final exam Thu. Dec. 12 2-5pm
 - Open-book, open-notes
 - Comprehensive, but with strong emphasis on the second half of the course
 - Sample final will be posted tomorrow
 - Past Gradiance exercises will be reopened as a study aid
 - Feel free to redo any; your grades have already been recorded

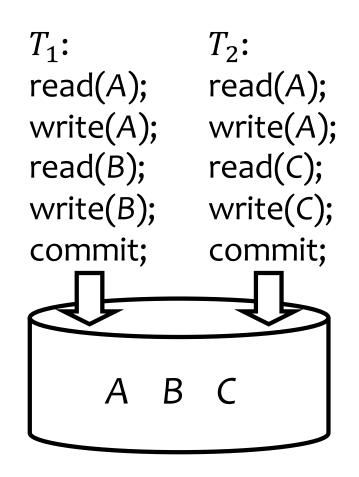

Review

- ACID
 - Atomicity: TX's are either completely done or not done at all
 - Consistency: TX's should leave the database in a consistent state
 - Isolation: TX's must behave as if they are executed in isolation
 - Durability: Effects of committed TX's are resilient against failures
- SQL transactions

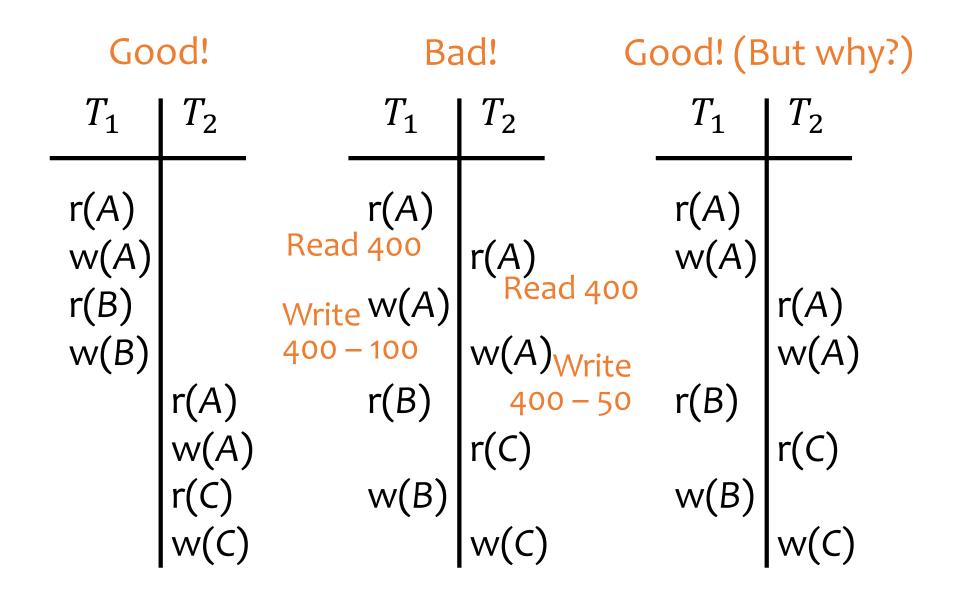

```
-- Begins implicitly
SELECT ...;
UPDATE ...;
ROLLBACK | COMMIT;
```

Concurrency control

• Goal: ensure the "I" (isolation) in ACID

Good versus bad schedules

Serial schedule

- Execute transactions in order, with no interleaving of operations
 - *T*₁.r(A), *T*₁.w(A), *T*₁.r(B), *T*₁.w(B), *T*₂.r(A), *T*₂.w(A), *T*₂.r(C), *T*₂.w(C)
 - *T*₂.r(A), *T*₂.w(A), *T*₂.r(C), *T*₂.w(C), *T*₁.r(A), *T*₁.w(A), *T*₁.r(B), *T*₁.w(B)

Isolation achieved by definition!

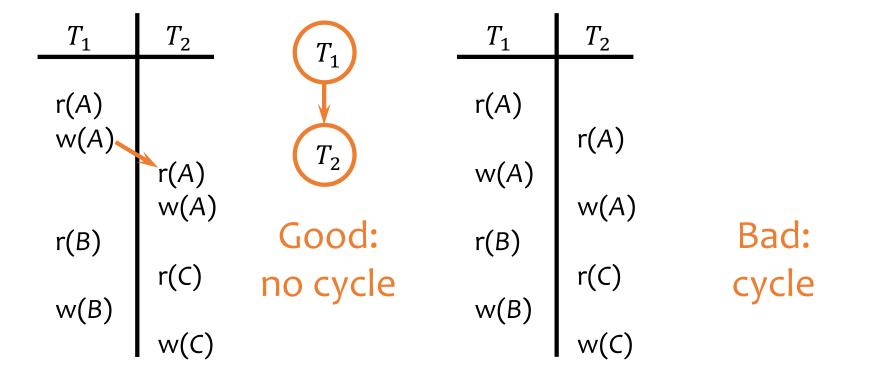

- Problem: no concurrency at all
- Question: how to reorder operations to allow more concurrency

Conflicting operations

- Two operations on the same data item conflict if at least one of the operations is a write
 - r(X) and w(X) conflict
 - w(X) and r(X) conflict
 - w(X) and w(X) conflict
 - r(X) and r(X) do not conflict
 - r/w(X) and r/w(Y) do not conflict
- Order of conflicting operations matters
 - E.g., if *T*₁.r(*A*) precedes *T*₂.w(*A*), then conceptually, *T*₁ should precede *T*₂

Precedence graph

- A node for each transaction
- A directed edge from T_i to T_j if an operation of T_i precedes and conflicts with an operation of T_j in the schedule

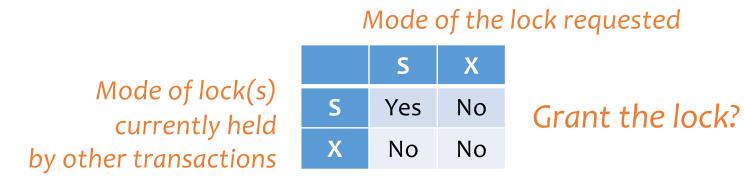

Conflict-serializable schedule

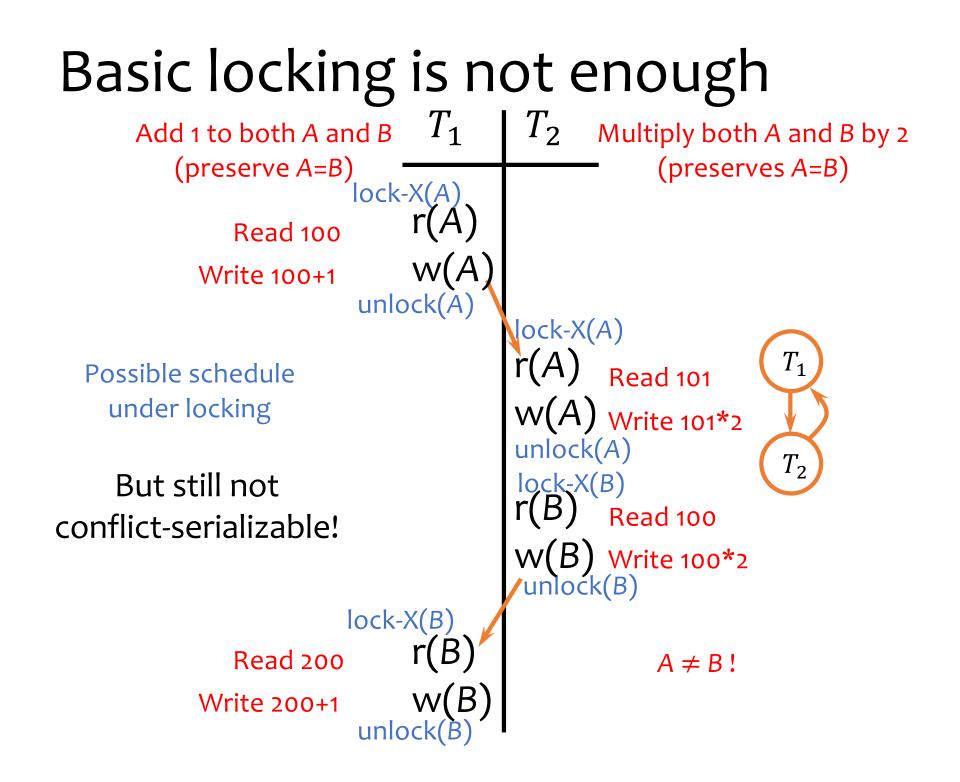

- A schedule is conflict-serializable iff its precedence graph has no cycles
- A conflict-serializable schedule is equivalent to some serial schedule (and therefore is "good")
 - In that serial schedule, transactions are executed in the topological order of the precedence graph
 - You can get to that serial schedule by repeatedly swapping adjacent, non-conflicting operations from different transactions

Locking

- Rules
 - If a transaction wants to read an object, it must first request a shared lock (S mode) on that object
 - If a transaction wants to modify an object, it must first request an exclusive lock (X mode) on that object
 - Allow one exclusive lock, or multiple shared locks

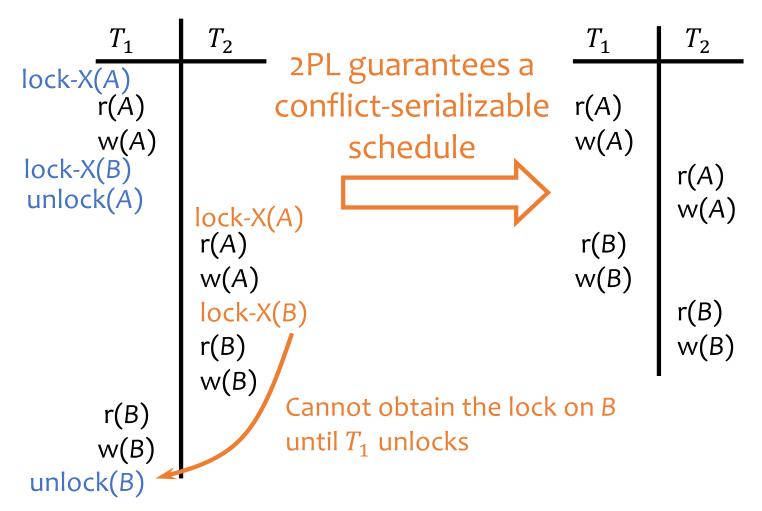

Compatibility matrix

Two-phase locking (2PL)

- All lock requests precede all unlock requests
 - Phase 1: obtain locks, phase 2: release locks

Remaining problems of 2PL

<i>T</i> ₁ r(A)	<i>T</i> ₂	• T_2 has read uncommitted data written by T_1
r(A) w(A)	r(A) w(A)	 If T₁ aborts, then T₂ must abort as well
r(B) w(B) Abort!		 Cascading aborts possible if other transactions have read data written by T₂

- Even worse, what if T_2 commits before T_1 ?
 - Schedule is not recoverable if the system crashes right after T_2 commits

Strict 2PL

- Only release locks at commit/abort time
 - A writer will block all other readers until the writer commits or aborts
- Used in many commercial DBMS

Recovery

• Goal: ensure "A" (atomicity) and "D" (durability)

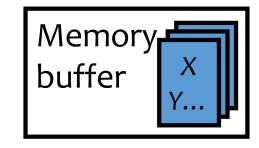

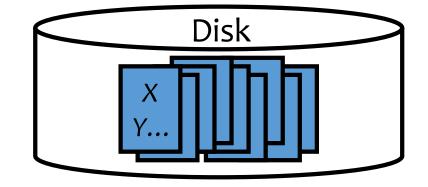

Execution model

To read/write X

- The disk block containing X must be first brought into memory
- X is read/written in memory
- The memory block containing X, if modified, must be written back (flushed) to disk eventually

Failures

- System crashes in the middle of a transaction *T*; partial effects of *T* were written to disk
 - How do we undo T (atomicity)?
- System crashes right after a transaction T commits; not all effects of T were written to disk
 - How do we complete *T* (durability)?

Naïve approach

- Force: When a transaction commits, all writes of this transaction must be reflected on disk
 - Without force, if system crashes right after T commits, effects of T will be lost
 - Problem: Lots of random writes hurt performance
- No steal: Writes of a transaction can only be flushed to disk at commit time
 - With steal, if system crashes before *T* commits but after some writes of *T* have been flushed to disk, there is no way to undo these writes
 - Problem: Holding on to all dirty blocks requires lots of memory

Logging

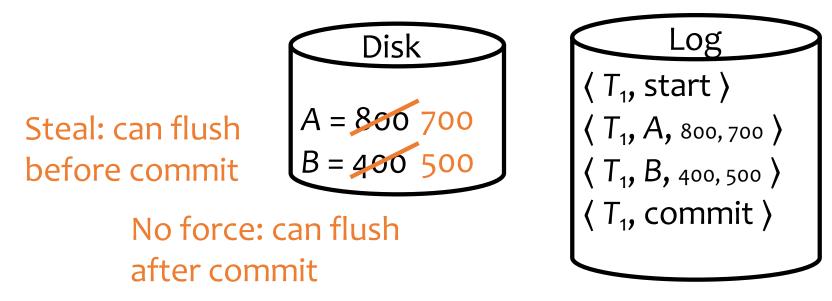

- Log
 - Sequence of log records, recording all changes made to the database
 - Written to stable storage (e.g., disk) during normal operation
 - Used in recovery
- Hey, one change turns into two—bad for performance?
 - But writes are sequential (append to the end of log)
 - Can use dedicated disk(s) to improve performance

Undo/redo logging rules

- When a transaction T_i starts, $\log \langle T_i, \text{start} \rangle$
- Record values before and after each modification:
 (T_i, X, old_value_of_X, new_value_of_X)
 - T_i is transaction id and X identifies the data item
- A transaction T_i is committed when its commit log record (T_i, commit) is written to disk
- Write-ahead logging (WAL): Before X is modified on disk, the log record pertaining to X must be flushed
 - Without WAL, system might crash after X is modified on disk but before its log record is written to disk—no way to undo
- No force: A transaction can commit even if its modified memory blocks have not be written to disk (since redo information is logged)
- Steal: Modified memory blocks can be flushed to disk anytime (since undo information is logged)

Undo/redo logging example

 $T_{1} \text{ (balance transfer of $100 from A to B)}$ read(A, a); a = a - 100;
write(A, a);
read(B, b); b = b + 100;
write(B, b);
commit;

No restriction (except WAL) on when memory blocks can/should be flushed

Checkpointing

• Where does recovery start?

Naïve approach:

- To checkpoint:
 - Stop accepting new transactions (lame!)
 - Finish all active transactions
 - Take a database dump
- To recover:
 - Start from last checkpoint

Fuzzy checkpointing

- Determine S, the set of (ids of) currently active transactions, and log (begin-checkpoint S)
- Flush all blocks (dirty at the time of the checkpoint) at your leisure
- Log (end-checkpoint begin-checkpoint_location)
- Between begin and end, continue processing old and new transactions

Recovery: analysis and redo phase

- Need to determine *U*, the set of active transactions at time of crash
- Scan log backward to find the last end-checkpoint record and follow the pointer to find the corresponding (start-checkpoint S)
- Initially, let U be S
- Scan forward from that start-checkpoint to end of the log
 - For a log record (T, start), add T to U
 - For a log record (T, commit | abort), remove T from U
 - For a log record (*T*, *X*, *old*, *new*), issue write(*X*, *new*)
 Basically repeats history!

Recovery: undo phase

- Scan log backward
 - Undo the effects of transactions in U
 - That is, for each log record (*T*, *X*, *old*, *new*) where *T* is in *U*, issue write(*X*, *old*), and log this operation too (part of the "repeating-history" paradigm)
 - Log (T, abort) when all effects of T have been undone
- An optimization
 - Each log record stores a pointer to the previous log record for the same transaction; follow the pointer chain during undo

Summary

- Concurrency control
 - Serial schedule: no interleaving
 - Conflict-serializable schedule: no cycles in the precedence graph; equivalent to a serial schedule
 - 2PL: guarantees a conflict-serializable schedule
 - Strict 2PL: also guarantees recoverability
- Recovery: undo/redo logging with fuzzy checkpointing
 - Normal operation: write-ahead logging, no force, steal
 - Recovery: first redo (forward), and then undo (backward)
