# Bayesian games and their use in auctions 

Vincent Conitzer<br>conitzer@cs.duke.edu

## What is mechanism design?

- In mechanism design, we get to design the game (or mechanism)
- e.g. the rules of the auction, marketplace, election, ...
- Goal is to obtain good outcomes when agents behave strategically (game-theoretically)
- Mechanism design often considered part of game theory
- 2007 Nobel Prize in Economics!
- 2012 Prize also related
- Before we get to mechanism design, first we need to know how to evaluate mechanisms

## Example: (single-item) auctions

- Sealed-bid auction: every bidder submits bid in a sealed envelope
- First-price sealed-bid auction: highest bid wins, pays amount of own bid
- Second-price sealed-bid auction: highest bid wins, pays amount of second-highest bid

## Which auction generates more revenue?

- Each bid depends on
- bidder's true valuation for the item (utility = valuation - payment),
- bidder's beliefs over what others will bid ( $\rightarrow$ game theory),
- and... the auction mechanism used
- In a first-price auction, it does not make sense to bid your true valuation
- Even if you win, your utility will be $0 .$. .
- In a second-price auction, (we will see next that) it always makes sense to bid your true valuation

| a likely <br> outcome for <br> the first-price <br> mechanism | bid 1: $\$ 5$ <br> bid 2: $\$ 4$ <br> 0 |
| :--- | :--- |

| a likely outcome <br> for the second- <br> price mechanism | bid 2: $\$ 510$ |
| :---: | :---: |
| 0 | bid 3: $\$ 1$ |

## Bidding truthfully is optimal in the Vickrey auction!

- What should a bidder with value v bid?
b = highest bid among otherbidders

Option 1: Win
the item at price
b, get utility v - b

> Would like to win if
> and only if $v-b>0$
> - but bidding truthfully accomplishes this!

Option 2: Lose the item, get
utility 0
We say the Vickrey auction is strategy-proof

## Collusion in the Vickrey auction

- Example: two colluding bidders
$v_{1}=$ first colluder's true valuation
$\mathrm{v}_{2}=$ second - price colluder 1 would pay when
colluder's true colluders bid truthfully
valuation
b = highest bid
among other bidders colluder 2 does not bid

Attempt \#1 at using game theory to predict auction outcome

- First-price sealed-bid (or Dutch) auction
- Bidder 1 has valuation 4, bidder 2 has val. 2
- Discretized version, random tie-breaking

|  | $\mathbf{0}$ |  |  |  | $\mathbf{1}$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{0}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ |  |  |
|  | 2,1 | 0,1 | 0,0 | $0,-1$ | $0,-2$ |
| $\mathbf{1}$ | 3,0 | $1.5, .5$ | 0,0 | $0,-1$ | $0,-2$ |
| $\mathbf{2}$ | 2,0 | 2,0 | 1,0 | $0,-1$ | $0,-2$ |
| $\mathbf{3}$ | 1,0 | 1,0 | 1,0 | $.5,-.5$ | $0,-2$ |
| $\mathbf{4}$ | 0,0 | 0,0 | 0,0 | 0,0 | $0,-1$ |
|  |  |  |  |  |  |

-What aspect(s) of auctions is this missing?

## Bayesian games

- In a Bayesian game a player's utility depends on that player's type as well as the actions taken in the game
- Notation: $\theta_{i}$ is player i's type, drawn according to some distribution from set of types $\Theta_{i}$
- Each player knows/learns its own type, not those of the others, before choosing action
- Pure strategy $s_{i}$ is a mapping from $\Theta_{i}$ to $A_{i}$ (where $A_{i}$ is i's set of actions)
- In general players can also receive signals about other players' utilities; we will not go into this

## Converting Bayesian games to normal form

| row player U type 1 (prob. 0.5) D | L | R | column player type 1 (prob. 0.5) | L R |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 4 | 6 |  | 4 | 6 |
|  | 2 | 4 |  | 4 | 6 |
|  | L | R |  | L | R |
| row player U | 2 | 4 | column player U | 2 | 2 |
| type 2 (prob. 0.5) D | 4 | 2 | type 2 (prob. 0.5) D | 4 | 2 |

|  | type 1: $L$ type 1: $L$ type 1: $R$ type 1: $R$ type 2: $L$ type 2: $R$ type 2: $L$ type 2: $R$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| type 1: U <br> type 2 : U | 3, 3 | 4, 3 | 4, 4 | 5, 4 |
| type 1: U <br> type 2: D | 4, 3.5 | 4, 3 | 4, 4.5 | 4, 4 |
| type 1: D type 2: U | 2, 3.5 | 3, 3 | 3, 4.5 | 4, 4 |
| type 1: D type 2: D | 3, 4 | 3, 3 | 3, 5 | 3, 4 |

exponential blowup in size

## Bayes-Nash equilibrium

- A profile of strategies is a Bayes-Nash equilibrium if it is a Nash equilibrium for the normal form of the game
- Minor caveat: each type should have >0 probability
- Alternative definition: for every i, for every type $\theta_{i}$, for every alternative action $\mathrm{a}_{\mathrm{i}}$, we must have:
$\Sigma_{\theta_{-i}} P\left(\theta_{-i}\right) u_{i}\left(\theta_{i}, \sigma_{i}\left(\theta_{i}\right), \sigma_{-i}\left(\theta_{-i}\right)\right) \geq$
$\Sigma_{\theta_{-i}} P\left(\theta_{-i}\right) u_{i}\left(\theta_{i}, a_{i}, \sigma_{-i}\left(\theta_{-i}\right)\right)$

## First-price sealed-bid auction BNE

- Suppose every bidder (independently) draws a valuation from [0, 1]
What is a Bayes-Nash equilibrium for this?
Say a bidder with value $v_{i}$ bids $v_{i}(n-1) / n$
Claim: this is an equilibrium!
Proof: suppose all others use this strategy
For a bid $b<(n-1) / n$, the probability of winning is (bn/(n-1)) $)^{n-1}$, so the expected value is $\left(v_{i}-b\right)(b n /(n-1))^{n-1}$ Derivative w.r.t. $b$ is $-(b n /(n-1))^{n-1}+\left(v_{i}-b\right)(n-1) b^{n-2}(n /(n-$ 1)) ${ }^{n-1}$ which should equal zero Implies $-b+\left(v_{i}-b\right)(n-1)=0$, which solves to $b=v_{i}(n-1) / n$

# Analyzing the expected revenue of the first-price 

 and second-price (Vickrey) auctions- First-price auction: probability of there not being a bid higher than b is $(\mathrm{bn} /(\mathrm{n}-1))^{\mathrm{n}}$ (for $\left.\mathrm{b}<(\mathrm{n}-1) / \mathrm{n}\right)$
- This is the cumulative density function of the highest bid
- Probability density function is the derivative, that is, it is $\mathrm{nb}^{\mathrm{n}-1}(\mathrm{n} /(\mathrm{n}-1))^{\mathrm{n}}$
- Expected value of highest bid is $n(n /(n-1))^{n} \int(n-1) / n b^{n} d b=(n-1) /(n+1)$
- Second-price auction: probability of there not being two bids higher than $b$ is $b^{n}+n b^{n-1}(1-b)$
- This is the cumulative density function of the second-highest bid
- Probability density function is the derivative, that is, it is $n b^{n-1}+n(n-1) b^{n-2}(1-b)-n b^{n-1}=n(n-1)\left(b^{n-2}-b^{n-1}\right)$
- Expected value is $(n-1)-n(n-1) /(n+1)=(n-1) /(n+1)$

## Revenue equivalence theorem

- Suppose valuations for the single item are drawn i.i.d. from a continuous distribution over [L, H] (with no "gaps"), and agents are risk-neutral
- Then, any two auction mechanisms that
- in equilibrium always allocate the item to the bidder with the highest valuation, and
- give an agent with valuation $L$ an expected utility of 0 , will lead to the same expected revenue for the auctioneer

## (As an aside) what if bidders are not risk-neutral?

- Behavior in second-price/English/Japanese does not change, but behavior in first-price/Dutch does
- Risk averse: first price/Dutch will get higher expected revenue than second price/Japanese/English
- Risk seeking: second price/Japanese/English will get higher expected revenue than first price/Dutch

# (As an aside) interdependent valuations 

- E.g. bidding on drilling rights for an oil field
- Each bidder i has its own geologists who do tests, based on which the bidder assesses an expected value $v_{i}$ of the field
- If you win, it is probably because the other bidders' geologists' tests turned out worse, and the oil field is not actually worth as much as you thought
- The so-called winner's curse
- Hence, bidding $v_{i}$ is no longer a dominant strategy in the second-price auction
- In English and Japanese auctions, you can update your valuation based on other agents' bids, so no longer equivalent to second-price
- In these settings, English (or Japanese) > secondprice > first-price/Dutch in terms of revenue

## Expected-revenue maximizing ("optimal") auctions [Myerson 81]

- Vickrey auction does not maximize expected revenue - E.g. with only one bidder, better off making a take-it-or-leave-it offer (or equivalently setting a reserve price)
- Suppose agent i draws valuation from probability density function $f_{i}$ (cumulative density $F_{i}$ )
- Bidder's virtual valuation $\psi\left(v_{i}\right)=v_{i}-\left(1-F_{i}\left(v_{i}\right)\right) / f_{i}\left(v_{i}\right)$ - Under certain conditions, this is increasing; assume this
- The bidder with the highest virtual valuation (according to his reported valuation) wins (unless all virtual valuations are below 0 , in which case nobody wins)
- Winner pays value of lowest bid that would have made him win
- E.g. if all bidders draw uniformly from [0, 1], Myerson auction = second-price auction with reserve price ½

## Vickrey auction without a seller

## ( $/$ (ziz 1 ) $=2$

## v(

( ${ }^{2}$ zin

## Can we redistribute the payment?

Idea: give everyone 1/n of the payment

not strategy-proof
Bidding higher can increase your redistribution payment

# Incentive compatible redistribution [Bailey 97, Porter et al. 04, Cavallo 06] 

Idea: give everyone $1 / n$ of second-highest other bid

## Strategy-proof

Your redistribution does not depend on your bid; incentives are the same as in Vickrey

## Bailey-Cavallo mechanism...

- Bids: $\mathrm{V}_{1} \geq \mathrm{V}_{2} \geq \mathrm{V}_{3} \geq \ldots \geq \mathrm{V}_{n} \geq 0$
- First run Vickrey auction
- Payment is V2
- First two bidders receive $\mathrm{V}_{3} / \mathrm{n}$
- Remaining bidders receive $\mathrm{V}_{2} / \mathrm{n}$
- Total redistributed: $2 \mathrm{~V} 3 / \mathrm{n}+(\mathrm{n}-$ 2) $V_{2} / n$
$\mathrm{R}_{1}=\mathrm{V}_{3} / \mathrm{n}$
$\mathrm{R}_{2}=\mathrm{V}_{3} / \mathrm{n}$
$\mathrm{R}_{3}=\mathrm{V}_{2} / \mathrm{n}$
$\mathrm{R}_{4}=\mathrm{V}_{2} / \mathrm{n}$
$\mathrm{R}_{\mathrm{n}-1}=\mathrm{V}_{2} / \mathrm{n}$
$\mathrm{R}_{\mathrm{n}}=\mathrm{V}_{2} / \mathrm{n}$

Is this the best possible?

## Another redistribution mechanism

- Bids: $\mathrm{V}_{1} \geq \mathrm{V}_{2} \geq \mathrm{V}_{3} \geq \mathrm{V}_{4} \geq \ldots \geq \mathrm{V}_{n} \geq 0$
- First run Vickrey
- Redistribution:

Receive 1/(n-2) * secondhighest other bid,

- $2 /[(n-2)(n-3)]$ third-highest other bid
- Total redistributed:

V2-6V4/[(n-2)(n-3)]

$$
\begin{aligned}
& R_{1}=V_{3} /(n-2)-2 /[(n-2)(n-3)] V_{4} \\
& R_{2}=V_{3} /(n-2)-2 /[(n-2)(n-3)] V_{4} \\
& R_{3}=V_{2} /(n-2)-2 /[(n-2)(n-3)] V_{4} \\
& R_{4}=V_{2} /(n-2)-2 /[(n-2)(n-3)] V_{3} \\
& \cdots \\
& R_{n-1}=V_{2} /(n-2)-2 /[(n-2)(n-3)] V_{3} \\
& R n=V_{2} /(n-2)-2 /[(n-2)(n-3)] V 3
\end{aligned}
$$
